COLLEGE OF PHYSICIANS
OF MINNESOTA
JANUARY 1973

Winter Scene

Frances E. Schaar, M.D.

JANUARY, 1973

Everybody experiences psychic tension.

Most people can handle this tension.

Some people develop excessive psychic tension and need your counseling,

and a few may need counseling
and the psychotropic action of Valium® (diazepam).

Before deciding to make Valium (diazepam) part of your treatment plan, check on whether or not the patient is presently taking drugs and, if so, what his response has been. Along with the medical and social history, this information can help you determine initial dosage, the possibility of side effects and the ultimate prospects of success or failure.

While Valium can be a most helpful adjunct to your counseling, it should be prescribed only as long as excessive psychic tension persists and should be discontinued when you decide it has accomplished its therapeutic task. In general, when dosage guidelines are followed, Valium is well tolerated (see Dosage). For convenience it is available in 2-mg, 5-mg and 10-mg tablets.

Drowsiness, fatigue and ataxia have been the most commonly reported side effects.

Until response is determined, patients receiving Valium should be cautioned against engaging in hazardous occupations requiring complete mental alertness, such as driving or operating machinery.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect.

Adults: Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 100 and 500. All strengths also available in Tel-E-Dose® packages of 1000.

STUART PHARMACEUTICALS | Division of ICI America Inc. | Wilmington, Del. 19899 | Pasadena, Calif. 91109

Sally's back in sew biz! After an arthritic flare-up.

Important Note: This drug is not a simple analgesic. Do not administer casually. Carefully evaluate patients before starting treatment and keep them under close supervision. Obtain a detailed history, and complete physical and laboratory examination (complete hemogram, urinalysis, etc.) before prescribing and at frequent intervals thereafter. Carefully select patients, including those responsive to routine measures, contraindicated patients or those who cannot be observed frequently. Warn patients not to exceed recommended dosage. Short-term relief of severe symptoms with the smallest possible dosage is the goal of therapy. Dosage should be taken with meals or a full glass of milk. Substitute alka capsules for tablets if dyspeptic symptoms occur. Patients should discontinue the drug and report immediately any sign of fever, sore throat, oral lesions, symptoms of blood dyscrasia, dyspepsia, epigastric pain, symptoms of anemia, black or tarry stools or other evidence of intestinal ulceration or hemorrhage, skin lesions, significant weight gain or edema. A one-week period is adequate. Discontinue in the absence of a favorable response. Restrict treatment periods to one week in patients over sixty.

Contraindications: Children 14 years or less, senile patients, history or symptoms of G.I. inflammation or ulceration including severe recurrent or persistent dyspepsia, history or presence of drug allergy, blood dyscrasias, renal, hepatic or cardiac dysfunction, hypertension, thyroid disease, systemic edema, stomatitis and salivary gland enlargement due to the drug, polymyalgia rheumatica and temporal arteritis, patients receiving other potent chemotherapeutic agents, or long term anticoagulant therapy.

Warnings: Age, weight, dosage, duration of therapy, existence of concomitant diseases, and concurrent potent chemotherapy affect incidence of toxic reactions. Carefully instruct and observe the individual patient, especially the aging (forty years and over) who have increased susceptibility to the toxicity of the drug. Use the most effective dosage. Weigh initially unpredictable benefits against potential risk of severe, even fatal, reactions. The disease condition itself is unaltered by the drug. Use with caution in first trimester of pregnancy and in nursing mothers. Drug may appear in cord blood and breast milk. Serious, even fatal, blood dyscrasias

Butazolidin® alka Geigy

Each capsule contains:
100 mg phenylbutazone USP
100 mg dried aluminum hydroxide gel USP
150 mg magnesium trisilicate USP

If it doesn't work in a week, forget it.

including aplastic anemia, may occur suddenly despite regular hemograms, and may become manifest days or weeks after cessation of drug. Any significant change in total white count, relative decrease in granulocytes, appearance of immature forms, or fall in hematocrit should signal immediate cessation of therapy and complete hematologic investigation. Unexplained bleeding involving CNS, adrenals, and G.I. tract has occurred. The drug may potentiate action of insulin, sulfonylurea, and sulfonamide-type agents. Carefully observe patients taking these agents. Nontoxic and toxic goiters and myxedema have been reported (the drug reduces iodine uptake by the thyroid). Blurred vision can be a significant toxic symptom. Worthy of a complete ophthalmological examination. Swelling of ankles or face in patients under sixty may be prevented by reducing dosage. If edema occurs in patients over sixty, discontinue drug.

Precautions: The following should be accomplished at regular intervals. Careful detailed history for disease being treated and detection of earliest signs of adverse reactions; complete physical examination including check of patient's weight; complete weekly (especially for the aging) or an every two week blood check; pertinent laboratory studies. Caution patients about participating in activity requiring alertness and coordination, as driving a car, etc. Cases of leukemia have been reported in patients with a history of short- and long-term therapy. The majority of these patients were over forty. Remember that arthritic-type pains can be the presenting symptom of leukemia.

Adverse Reactions: This is a potent drug, its misuse can lead to serious results. Review detailed information before beginning therapy. Ulcerative esophagitis, acute and reactivated gastric and duodenal ulcer with perforation and hemorrhage, ulceration and perforation of large bowel, occult G.I. bleeding with anemia, gastritis,

epigastric pain, hematemesis, dyspepsia, nausea, vomiting and diarrhea, abdominal distention, agranulocytosis, aplastic anemia, hemolytic anemia, anemia due to blood loss including occult G.I. bleeding, thrombocytopenia, pancytopenia, leukemia, leukopenia, bone marrow depression, sodium and chloride retention, water retention and edema, plasma dilution, respiratory alkalosis, metabolic acidosis, fatal and nonfatal hepatitis (cholestasis may or may not be prominent), petechiae, purpura without thrombocytopenia, toxic pruritus, erythema nodosum, erythema multiforme, Stevens-Johnson syndrome, Lyell's syndrome (toxic necrotizing epidermolysis), exfoliative dermatitis, serum sickness, hypersensitivity angitis (polyarteritis), anaphylactic shock, urticaria, arthralgia, fever, rashes (all allergic reactions require prompt and permanent withdrawal of the drug), proteinuria, hematuria, oliguria, anuria, renal failure with azotemia, glomerulonephritis, acute tubular necrosis, nephrotic syndrome, bilateral renal cortical necrosis, renal stones, ureteral obstruction with uric acid crystals due to uricosuric action of drug, impaired renal function, cardiac decompensation, hypertension, pericarditis, diffuse interstitial myocarditis with muscle necrosis, perivascular granulomata, aggravation of temporal arteritis in patients with polymyalgia rheumatica, optic neuritis, blurred vision, retinal hemorrhage, toxic amblyopia, retinal detachment, hearing loss, hyperglycemia, thyroid hyperplasia, toxic goiter, association of hyperthyroidism and hypothyroidism (causal relationship not established), agitation, confusional states, lethargy; CNS reactions associated with overdosage, including convulsions, euphoria, psychosis, depression, headaches, hallucinations, giddiness, vertigo, coma, hyperventilation, insomnia; ulcerative stomatitis, salivary gland enlargement (B)98-146-070-G

Serious side effects do occur. Select patients carefully (particularly the elderly) and follow them closely in line with the drug's precautions, warnings, contraindications and adverse reactions

For complete details, including dosage, please see full prescribing information.

President's Letter

A Beginning

One second ticks by and another year begins. The public media "wrap up" the old year for us, as if to bury it, then look to the future with hope. The newness is the promise of the future, and by habit we expect it to be more rewarding. Thus we celebrate the new year.

It seems apparent that our parade of passing years should teach us that we live *now*, not in the past or the future. What we do, what we feel, what we hope for or regret exists in the present. Right now we can use the past and plan for the future, or we can be trapped into regretting the past and dreaming of better things to come. Each of us has that vitalness we call life and each of us must decide how we live it.

Our family is presently grieving over the death of Cheryl, whose life illustrated that we live day by day. At eighteen she was a vital force whose sensitiveness to others caused her great inner turmoil but whose fortitude never allowed her to cease the struggle to find her place in our world. We never fully realized the number of lives that she touched, the help she offered others. Can a better tribute be paid to any human than that he used what he was given to the best he was able? That is my wish for the new year.

To each of you, a beginning. The full use of your talents; each day a vitalness that is life itself; and while it may or may not be happy, a year to remember with warmth for it indeed was LIVED!

George B. Martin

President
Minnesota State Medical Association

Relocating? see the lakeview medical building

- * 15 minutes from downtown Minneapolis
- * Newly remodeled
- * Unlimited free parking
- * Diagnostic facilities available

"The existing unit, shown here will be replaced by an entirely new Lakeview Medical Building in 1974."

On the grounds of Glenwood Hills Hospital, the Lakeview Medical Building offers newly remodeled facilities carefully planned to meet your needs. This small, multiple-specialty clinic is now open for your inspection.

Opinion & Dialogue

Doctor of Medicine

Louis Lasagna, M.D.
Professor and Chairman
Department of
Pharmacology & Toxicology
University of Rochester
School of Medicine
and Dentistry

Obviously, many drugs are given concomitantly. Whether it makes sense to combine medications in one preparation, be it capsule, tablet, or liquid, is a question that can be answered only by examining the advantages and disadvantages in the individual case.

Among the advantages is, first of all, convenience. The more medications that are taken concurrently and the more complicated the directions, the less likely the patient is to take medications accurately. From the standpoint of convenience and accuracy, and economy as well, you can make an important case for putting medications together in one preparation, as long as they are compatible.

By the same token, when you prescribe a properly tested and rational combination, you should have less worry about pharmaceutical or pharmacological compatibility—and about reasonable dosage ratios as well. Compatibility of the formulation should be demonstrated in the laboratory and clinic before the product is available for prescription—which is more than can usually be said for

the physician's own spontaneous creations. And, the dosage ratios employed in rational precompounded combinations are designed to meet the needs of substantial numbers of "typical" patients.

There is no doubt that many "atypical" patients are to be found, and for them the prefabricated combination must be rejected. But that hardly argues for eliminating rational combinations from the market. Think, for example, of the problems that would arise if the components of widely accepted combinations, like the oral contraceptives and the diuretic-antihypertensives, always had to be prescribed, purchased and ingested separately.

One disadvantage that comes to mind is some doctors' unawareness of the ingredients a given combination contains. For example, a doctor might know that a patient is allergic to aspirin but forget that a certain analgesic mixture, which he knows only by its trade name, contains aspirin. His prescription, then, causes considerable discomfort, to say the least. This problem is a function of physician education, rather than of combination therapy as such. Improving doctors' knowledge about all medicaments they prescribe is a problem that deserves tackling on its own.

Another accusation leveled at combination drugs is that they encourage sloppiness of diagnosis and treatment. In many cases, however, a combination may prove to be the most effective choice. A good ex-

ample of the usefulness of combinations appears in a recent article in the *Journal of Chronic Diseases* on the efficacy and side effects of an antihypertensive containing three ingredients, in which the track records of the combination drug and the individual ingredients were compared. Interestingly enough, whether the drugs were given individually or together, incidence and severity of side effects were the same. But blood pressure control was invariably better when the drugs were taken in one combination tablet than when they were taken separately (in "titratable" dosage) or in two or three different tablets.

Deciding which combinations constitute rational therapy obviously leads to a discussion of who is to determine which should be used and which should not. Realistically, I think combinations should be evaluated somewhat differently if they are old and established or new and untried.

In today's regulatory atmosphere, there is no possibility of a new combination being put on the market without a substantial amount of acceptable evidence in the form of controlled trials that show it to be safe and efficacious. On the other hand, I believe a different set of standards should apply to combination preparations that have been around for a long time. In other words, physician acceptance over a long period should be given some weight as evidence of the efficacy and safety of these drugs.

The FDA, however, does not seem to share this attitude. It often requires, for these older products, controlled trials that will monopolize the time of already overtired investiga-

tors and cost a great deal of money. I wish we could agree on a "grandfather clause" approach to preparations that have been in for a number of years that have an apparently satisfactory track record.

For example, I think some of the antibiotic combinations that were taken off the market by the FDA performed quite well. I'm thinking particularly of penicillin-streptomycin combinations that patients—especially surgical patients—were given in injection. This made less discomfort for the patient, less demand on nurses' time, and fewer opportunities for dosing errors. To take such preparation off the market doesn't seem to be good medicine, unless actual age showed a great deal of harm from the injection (rather than the pro use) of the combination.

The point that should be emphasized is that there are both rational and irrational combinations. The real question is, who should determine which is which? Obviously, the FDA may play a major role in making this determination. In fact, I don't think it could avoid taking the ultimate responsibility, but it should enlist the help of outside physicians and experts in assessing the evidence and in making the ultimate decision.

Maker of Medicine

V. Clarke Wescoe, M.D.
President
Winthrop Laboratories

If two medications are used effectively to treat a certain condition, and it is known that they are compatible, it clearly is useful and convenient to provide them in one dosage form. It would make no sense, in fact, it would be pedantic, to insist they always be prescribed separately. To avoid the appearance of pedantry, the "expert" decries the combination because it is a fixed dosage form. When the "expert" evokes the concept of fixed dosage form he obscures the fact that single-ingredient pharmaceutical preparations are also fixed dosage forms. By a singular semantic exercise he imparts a pejorative meaning to the term "fixed dose" only when he uses it with respect to combinations. What is ignored is the simple fact that only in the best of circumstances does any physician attempt to titrate an exact therapeutic response in his patient. It is quite possible that some aches and pains will respond to 500 mg. of aspirin yet that fact does not militate against the usefulness of a 650 mg. dose. The other semantic ploy often called into play is to prescribe a combination product as rational or irrational. Take antibiotic mixtures, a source of much of the criticism generated against

combinations generally. Obviously, no one should be exposed willy-nilly to the potential side effects of two or three antibiotics when only one is needed. At the same time there are cases where it is prudent to prescribe more than one. The clinician is the judge in these circumstances, as he should be.

There is no clear definition of the word rational. Most persons, I suppose, would find it synonymous with reasonable, but in many circumstances it may best be defined as the opinion of those in power at the moment.

Other factors govern combination therapy, not the least of which has been its broad use by practicing physicians anxious to achieve convenience in prescribing, to reduce medication error, and to save money for their patients. Combinations clearly have met the test on all three counts.

I have been impressed by studies showing that the rate of error climbs markedly with the number of medications to be taken, even with sophisticated patients. When medically justified, therefore, this factor alone supports the logic of combination therapy.

The cost argument for combinations appears to be irrefutable. In 1971, R. A. Gosselin studied the 71 combination products (excluding oral contraceptives) among the 200 most prescribed drugs. The study found that if all 71 products were discontinued, and if each ingredient in these combinations were prescribed separately, the price of medicines to patients would jump by \$443.2 million on a national basis! At a time when the cost of medical care is under so much fire, it would be nonsensical to boost costs without clearly irre-

futable medical reasons.

The part played by government on this question, of course, is fundamental. The FDA should play a role in determining which combinations are reasonable. That role, as defined by law and regulation, is to ensure that any medication on the market is safe and effective in line with its label claims. Certainly combinations are entitled to as much consideration as single entities—neither more nor less. So long as the addition of one drug to another does not make either less safe, or less effective, so long as they are compatible in a formulation, we have a reasonable product. It makes no sense to recommend the use of two products for certain conditions and to deny their being combined in a single form. An unhappy side effect of the problem concerns the efficacy panel discussions of many products submitted for review. The term "effective, but" has been freely interpreted to mean "ineffective" in toto, regardless of the merit of the individual drugs. This interpretation has placed numerous useful combination products in needless jeopardy.

In reading the actual reports of the review panels, it seems clear that some of the ratings were based less on scientific research and clinical observation than on the "informed" opinions of the panelists. These "informed" opinions were accepted at face value, while

the "informed" opinions of others who had used the products were rejected. All of this put combination products into a sort of scientific never-never land.

It should be kept in mind by all, government as well as others involved in our health care system, that advances in therapy are seldom made in leaps and bounds but rather by small painstaking steps—and that some of these steps have resulted from research in combination drugs as well as with single entities. Given the near-infinite biologic variation in patient response, this is hardly surprising to clinicians. It should not be to regulatory agencies either.

In the end, the practicing physician is in the best position to decide if a particular combination makes sense. Such a decision should not be made exclusively by those whose responsibility for continuing clinical care is limited. Clinicians are the best judges of efficacy because the ultimate proof of any product's effectiveness is acceptance by physicians who have observed its actions in patients over time. The corollary statement may be made about over-the-counter medicines, which would not long survive if they failed to afford the relief the user anticipates. That the antihistamine in a "cold" remedy may not *always* be necessary is no reason to proscrib the combination generally.

Opinion & Dialogue

What is your opinion, doctor?

We would welcome your comments.

Infectious Hepatitis after Ingestion of Raw Clams

LUKAS GUIDON, M.D. AND CLAUS A. PIERACH, M.D.

INFECTIONOUS HEPATITIS is most frequently transmitted by person-to-person contact. It is well known that contaminated water, milk, and food can be the vehicle for the infective agent. In the last six years, several epidemics of infectious hepatitis have been traced to clams and oysters, harvested from contaminated waters, and then ingested raw or steamed.

Although raw shellfish is not on the daily menu in the Mid-West, we have to consider this route of transmission because of the increasing tourism and interest in international food and increased pollution of the seawater.

It is the purpose of the following case report to remind physicians and gourmets that ingestion of raw shellfish may be harmful.

Case Report

A 70-year-old white man came to the outpatient clinic of Northwestern Hospital on April 19, 1972 complaining of general malaise and intermittent febrile episodes with shaking chills for the last few days.

His past medical history was essentially unrevealing. He never had blood transfusions, nor had he had jaundice or contact with jaundiced persons, and he had noted no color change in his urine or stool.

In the beginning of March, 1972, he was in Florida, where on one occasion he ate a few raw clams. Since February, 1972, he had been taking Parnate® 10 mg tid, and Stelazine® 2 mg bid, for depression.

Physical examination on admission showed the patient to be well oriented, well nourished, and in no acute distress. Pulse was 80/min regular, blood pressure 110/75 mm Hg, respirations 18/min, temperature 37.2°C. There was mild jaundice of the sclerae, and a slightly tender liver edge, only palpable on deep inspiration.

The most important laboratory results on admission, during hospitalization, and after discharge are shown in the Figure.

Hemoglobin remained between 11.9 gm% and 14.5 gm%, white blood cell count between 3200 and 5000 cells/mm.³ Serum NH₃ varied between 91 and 119 mcg%, serum iron between 107 and 180 mcg%, and iron-binding

capacity between 220 and 472 mcg%. Serum calcium, phosphate, glucose, uric acid, proteins, and electrolytes stayed within normal limits. Australia antigen and antibody was negative (isoprecipitin technique). The blood could not be tested for epidemic hepatitis associated antigen—Milan (EHAA). Urine was initially positive for bilirubin, and 24-hour urines contained between 0.5 mg and 4.6 mg urobilinogen. Urobilinogen in a random stool sample was 62.4 mg/100 gm on 4/26/72. Stool examinations showed occult blood up to 4+, but mostly 1+ or negative. Electrocardiographic tracings showed left axis deviation with signs of a possible old inferior infarct.

Infectious hepatitis was diagnosed and the patient was treated with bedrest, intravenous infusions of 10% Levulose in water with Vitamin B₁ 10 mg, Vitamin B₂ 10 mg, Niacinamide 250 mg, Pyridoxine 5 mg, and ascorbic acid 500 mg per liter given 75 cc/hour. Parnate® and Stelazine® were discontinued. Although the patient developed a deep jaundice in the first week, he improved from his severe hepatitis with remarkable rapidity. His appetite picked up after three days, and he was discharged after 17 days, in good condition.

We had considered in our patient the possibility of a reaction to Parnate® and/or Stelazine®. The reported cases with jaundice in connection with these drugs had either typical signs of cholestasis with only mild evidence of liver damage, two to four weeks after the drugs were started, or signs of hypersensitivity, such as fever, eosinophilia, skin eruptions, and hepatosplenomegaly. In our case, a chemical induced jaundice is unlikely, since neither of these reactions were present.

Discussion

Epidemic jaundice has been recognized for many centuries. Person-to-person contact is the most frequent route of transmission of infectious hepatitis (Virus A). However, since the nineteenth century there have been epidemics of jaundice that have been attributed to water-borne transmission. Mosley, in 1959, reviewed the literature about water-borne epidemics of infectious hepatitis.¹ Between 1895 and 1957, he found 33 reports of 28 epidemics attributed to drinking of contaminated

From the University of Minnesota Unit for Teaching and Research in Internal Medicine at Abbott-Northwestern Hospital, Minneapolis, Minnesota.

water. Besides water-borne epidemics, there are several food-transmitted epidemics of infectious hepatitis reported.²⁻¹³ In three epidemics, unpasteurized milk was the presumed vehicle.^{2,3,8} In five other epidemics it was custard,⁶ sandwiches with raw meat, cheese and garnishes,⁹ mayonnaise in potato salad,¹¹ orange juice,¹² roast pork, and green salad.¹³

Infectious hepatitis (Virus A) can also be transmitted by parenteral route^{16,17} (Table 1). Shellfish, living in contaminated water, are likely to harbor the virus. In 1956, the first epidemic of hepatitis attributed to the ingestion of raw shellfish was recognized in Sweden.¹⁸ For some of the patients who had eaten oysters on only one occasion, it

was possible to determine the exact date of consumption, as well as the date of onset. The length of the incubation period varied from 18 to 44 days, with an average length of 29 days. There was no significant difference in the length of the incubation period between those who had eaten only one or two oysters and those who had eaten more than six. It could be concluded that the consumption of one single oyster was sufficient to produce hepatitis with clinical symptoms. The majority of the cases belonged to the highest social groups, and more than 50% were adult males. This episode attracted wide attention, but little apprehension that shellfish-associated hepatitis might occur in the United States. In 1961, however, two shellfish-associated epidemics were rec-

Figure—Graphic presentation of the laboratory data in our patient with hepatitis.

ognized in this country. The first was traced to raw oysters, and accounted for 80 cases in Mississippi and Alabama, and four additional cases in three other states.¹⁹ The second, related to the ingestion of raw clams, consisted of 459 cases in New Jersey, and an undetermined number in other states.¹⁰ Early in 1963, an unusual proportion of hepatitis patients at each of two hospitals, one in Connecticut and the other in New Jersey, reported having eaten raw clams. Local, state, and federal agencies began epidemiologic investigations which eventually documented two additional major epidemics of clam-associated infectious hepatitis, with 119 and 252 cases respectively.^{20,21}

TABLE 1

Transmission of Infectious Hepatitis (Virus A)

1. Person to person, fecal-oral route
2. Ingestion of contaminated water or food, including raw shellfish from polluted and contaminated water
3. Parenteral

Table 2 summarizes the epidemics and sporadic cases of shellfish-associated infectious hepatitis in the literature. We found record of 1623 cases of infectious hepatitis attributed to the ingestion of raw or steamed shellfish between 1955 and 1971.

Epidemiological Characteristics

All epidemics showed a similar pattern:

1. The patients started to have symptoms of infectious hepatitis 15-60 days after ingestion of the shellfish. Fifty percent of the patients got sick between day 29 and day 36.
2. The infective shellfish could be traced in most cases to a polluted area of the coast.
3. During these epidemics of infectious hepatitis, the number of patients infected by shellfish, and the number of patients who acquired the disease by person-to-person contact was about the same, i.e., ingestion of raw shellfish or steamed clams seemed to be as common a

source of infection as contact with jaundiced persons.

4. Fried shellfish have not been found to transmit infectious hepatitis.
5. Australia antigen was negative in all patients, when tested. None of the cases was tested for EHAA (Epidemic hepatitis associated antigen-Milan).

Clinical Characteristics and Features of Infectious Hepatitis Caused by Ingestion of Raw Shellfish

All ages were affected, but as expected, adult males of the higher social groups made up the biggest percentage. The onset of symptoms was usually abrupt, but the disease generally mild, although some of the adult cases had prolonged icterus which lasted four to six weeks. To our knowledge, there have been no cases reported of chronic active hepatitis after infectious hepatitis caused by ingestion of raw shellfish. There were only a few fatalities. Only icteric cases were included, but many anicteric cases were suspected by impaired liver function tests. Frequently the fever rose above 38° C (100.4° F). Abdominal pain and arthralgia were infrequent. Laboratory tests usually showed positive urine bilirubin, elevated serum bilirubin, abnormal cephalin flocculation and thymol turbidity, marked elevation of SGOT and normal or only mildly elevated alkaline phosphatase.

Once the jaundice is present, it may be difficult to differentiate between infectious and serum hepatitis. Table 3 compares the typical features of infectious and serum hepatitis.

Comment

Oysters and clams are the only types of seafood commonly ingested uncooked. They are also one of the few food items in which the entire animal, including the gastrointestinal tract and its contents, are eaten. These two facts in combination with the ecology and physiology of these shellfish

TABLE 2
Cases of Seafood Related Hepatitis

Year	Type of Shellfish	Number of Cases	Localization	Author
1955	Oysters	629	Sweden	Roos ¹⁸
1961	Oysters	84	Miss/Ala	Mason/McLean ¹⁹
1961	Clams	459	NJ/NY	Dougherty/Altman ¹⁰
1963	Clams	252	Pa/NJ	Commun. Dis. Center ²⁰
1963	Clams	119	Conn/RI	Commun. Dis. Center ²¹

uniquely equips them for transfer of disease with fecal-oral route of spread.^{25,26}

A question of practical significance relates to the amount of cooking necessary to inactivate the virus. Limited numbers of transmission experiments in human volunteers have shown that the agent can withstand heating to 56° C (132.8° F) for thirty minutes. Unfortunately, many people

consider the mollusk to be fully cooked when the shell opens, although it has been observed that the internal tissue temperature of steamed soft-shell clams at the time of the shell opening is always below 70° C (158° F).²⁷ It is also held that the shorter the steaming period, the more succulent the shellfish.

Until the agent of infectious hepatitis is avail-

TABLE 3
Different Features of Infectious Hepatitis and "Serum Hepatitis"

Feature	Infectious Hepatitis	"Serum Hepatitis"
Route of Infection	Mainly fecal-oral, but also parenteral	Mainly parenteral, but also fecal-oral
Incubation Period	29-36 days, no difference in oral or parenteral route of infection	35-200 days ^{16,17} 65 days after parenteral exposure 98 days after oral infection
Clinical Features:		
Onset	Usually abrupt	Usually slow and insidious
Anorexia	Present	Usually absent
Abdominal pain	Infrequent	Frequently appearing after 1-2 weeks
Ambulation	Usually non-ambulant	Usually ambulant
Arthralgia	Usually insignificant or absent	As early as three to four weeks before the onset of jaundice, particularly in small joints and at night
Ratio of icteric to anicteric	About 1:1 in adults About 1:12 in children	About 1:100
Fever over 38° C	Common	Less common
Mortality rate	0.1-0.3% in young adults, higher in older individuals, especially in women after menopause	Up to 1%
Duration of infectivity and carrier state	Blood: for days Feces: for weeks to months	Blood: for months to years Feces: undetermined
Prophylactic value of gamma globulin	Good	Variable results
Diagnostic biochemical and serological tests:		
SGOT	Spiking rise and short duration of elevated activity (1-3 weeks)	Gradual rise and long duration (up to six months)
Thymol turbidity IgM	Consistently abnormal High increase 3-4 days before abnormal SGOT, return to normal 5-35 days later	Relatively normal Slight increase during acute stage
Au Antigen/Antibody	Negative	Positive 30-80 days after exposure in blood, urine & feces, only transient in 65%
EHAA (Milan)	Positive ²⁴	Negative

able for in-vitro studies, the exact duration of cooking necessary to ensure safety from hepatitis will not be known. Only frying of the shellfish appears certain to inactivate the virus.

The continued occurrence of epidemics of shellfish-related hepatitis indicates the need for strict enforcement of regulations governing harvesting,

storing, and distribution of mollusks. This becomes more and more difficult with the increase of pollution of the seawater along the coasts. Therefore, it is very important to obtain a careful history from each patient with viral hepatitis, in order to detect an epidemic as early as possible.

Hamartoma of the Hepatic Bile Ducts

LUIS H. TOLEDO-PEREYRA, M.D., ROBERT L. GOODALE, JR., M.D.,
JOHN S. NAJARIAN, M.D. AND PATRICK WARD, M.D.

BENIGN NEOPLASM of the extrahepatic ducts are rare. As of 1962⁶ only 73 histologically confirmed cases have been recorded. In 29 cases reported by Chu in 1950,⁴ 16 were adenomas, 10 papillomas or polyps, two neuromas, and one fibroma. Other benign tumors of the extrahepatic biliary ducts include: a leiomyoma, a cystic papilloma¹ and granular cell myoblastoma.⁵ The largest benign tumor reported was a 750 gm papillomatous tumor from the common duct of a four year old child.⁹ This case presentation is the second reported hamartoma of the hepatic bile ducts⁶ and demonstrates some unusual difficulties associated with surgical removal.

Case Report

An 18-year-old obese female was admitted in July, 1970, because of painless jaundice, dark urine, light stools, weakness and anorexia. There was no family history of jaundice, no known exposure to hepato-toxic agents. Oral cholecystogram revealed a non-visualizing gallbladder. An exploratory laparotomy and cholecystectomy was done on July 31, 1970. At the time of surgery a gallbladder without stones was found. A common duct exploration was then performed and a soft, smooth, brownish tumor mass was found in the common hepatic duct at the junction of right and left hepatic ducts. This mass was removed grossly by curette and a T-tube was placed in the common duct. Histologically this was thought to be a primary hamartoma. Jaundice subsided postoperatively. Eight months postoperatively however, a T-tube cholangiogram showed apparent re-growth of the tumor (Figure 1) and jaundice recurred.

Second Admission

The patient was then referred to the University of Minnesota Hospitals. Liver function studies confirmed obstructive jaundice. Total bilirubin was 5.9mg%. Alkaline phosphatase was 283 King Armstrong Units. LDH was 197, SGOT was 198. A liver biopsy showed periportal fibrosis with bile stasis consistent with moderate biliary cirrhosis. On April 1, 1971 after losing 50 lbs, the patient was re-explored and the hilus of the liver was

incised for exposure of the right and left intrahepatic ducts. The common and left hepatic ducts were opened linearly 3 cm. A smooth brown tumor 2 cm diameter attached to the medial wall of the left hepatic duct was removed by cannon endarterectomy instrument. The site of tumor attachment to the wall was electrofulgurated to destroy residual tumor cells. (The histologic report was hamartoma, Figure 2). The two split limbs of a number 26 Fr T-tube were inserted in each hepatic duct to act as stents for the primary duct repair.

Her postoperative course was complicated by the development of acute renal tubular necrosis secondary to Cephaloridine therapy. Fortunately, tubular function returned rapidly, and she was discharged from the hospital on the twenty-second postoperative day. Her liver and renal function studies were normal at the time of discharge. A T-tube cholangiogram two months after surgery, showed filling of both ducts and no evidence of recurrence (Figure 3). The T-tube was removed 10 months after surgery.

Fig. 1—T-tube cholangiogram shows dilatation of the common duct, a filling defect of the left hepatic and common duct and complete obstruction of the right hepatic bile duct from the hamartoma.

Department of Surgery and Pathology, University of Minnesota Hospitals, Minneapolis, Minnesota.

The authors are grateful to Dr. R. H. Meyer, of Faribault, Minnesota for referring this patient and for permitting us to use the material for publication.

Address reprint requests to: Dr. Toledo-Pereyra, Department of Surgery, P.O. Box 223, University Hospitals, Minneapolis 55455.

Third Admission

The patient was re-admitted on November 6, 1972 with mild jaundice and pruritus. A retrograde biliary ductogram was performed with an Olympus JF Duodenoscope. A lobulated hepatic filling defect in the common hepatic duct was found. The common duct was re-explored and a polypoid tumor was found arising from the inferior aspect of the posterior segment of the right hepatic duct. The histological diagnosis again was hamartoma. Because of the benign histological diagnosis and the intrahepatic location of this tumor, no further resection was attempted at this time. A #12 Lahey latex tube was left in place. This patient has made a satisfactory convalescence and jaundice has subsided.

Discussion*Pathology*

Benign neoplasms of the extrahepatic ducts are rare, difficult to diagnose, and to treat. Of the 29 cases histologically confirmed by Chu (1950) only two were successfully treated surgically.⁴ In no case was the correct diagnosis made pre-operatively.

In the most recent review by Dowdy⁶ (1962) 43 authenticated additional cases were uncovered. Of those cases four were multi-centric. All four were papillomas in intrahepatic ducts as well as in extrahepatic ducts, and of these there was one survivor. The intrahepatic papilloma in that case was confined to the left lobe of the liver and a left hepatectomy was successfully performed.²

Fig. 2—(X90) Polypoid hamartoma covered by flat cuboidal bile duct epithelium. Glandular spaces are also lined by epithelium of this type. The stroma is composed of fibrous and smooth muscle elements. No mitotic figures are seen.

Fig. 3—T-tube cholangiogram two months postoperative demonstrating normal filling of both hepatic and common bile ducts.

Symptoms and Diagnosis

In Dowdy's review,⁶ jaundice was the predominating symptom appearing in 90% of the cases. In 42% of the cases jaundice was intermittent. Pain was the next most common symptom (81%). Other symptoms occurring less frequently included dyspepsia, fever, chills, weight loss and hemobilia.^{3,4,6,8,10} The liver was enlarged and palpable in a large percent of the cases due to an obstruction of the bile ducts. The gallbladder was enlarged and palpable as a rule when the tumor was below the origin of the cystic duct and obstruction was present. Only rarely were these tumors palpable. One should be suspicious when intermittent jaundice is present with a normal cholecystogram. Intravenous cholangiography is not too helpful since most of the patients are deeply jaundiced at the time of the study.⁴ Even at the time of surgery, it may be difficult to find these benign tumors because they are soft. A probe may be easily passed through the area of the tumor, therefore, palpation of the bile ducts and sometimes duodenotomy are important in detecting them. The treatment of choice is local excision.

The hamartoma reported by Dowdy et al. was a 43-year-old white woman with an obstructive jaundice of one month duration. There was marked liver damage. The operative findings were:

cholestasis of the liver, multiple bile retention cysts and a grayish, lobulated polypoid hamartoma protruding into the lumen of the hepatic bile duct. After removal of the tumor a T-tube was left in place and removed 18 months later, after a normal cholangiogram. The present case represents the second hamartoma of the biliary ductal system reported.

The items of interest in our case were the initial findings which were atypical of calculous disease. Painless jaundice in a young patient with a non-calculous gallbladder and absence of pancreatitis should alert the surgeon to the possibility of tumor in the biliary tree. The advent of fiberoptic duodenoscopy with retrograde biliary ductograms may facilitate the diagnosis.

It is also apparent that benign tumors can grow at a rapid rate, and re-obstruct the biliary tree. The intrahepatic location of tumors can be such as to cause difficulty in removal. Often incision deep into the hepatic hilus may be necessary as in this case. Future recurrence of tumor in our case may indicate the necessity of a hepatic lobectomy, however at this point we are unable to state which lobe may have to be removed. We believe that these episodes of obstructive jaundice are on the basis of multi-centric tumor rather than recurrence from the same primary.

Pediatric's Day

Pediatric Day will be held March 3, 1973 at the Mayo Clinic. The program will be comprised of a series of talks by the faculty relating to problems in pediatric practice. Doctor Warren E. Wheeler, Professor and Chairman of the Department of Pediatrics, University of Kentucky will be the guest speaker and will talk on the approach to problems of failure to thrive. For information, write Dr. E. C. Burke, Mayo Clinic, Rochester, Minnesota 55901.

Melanomatous Meningiomas

LEONARD A. TITRUD, M.D.

TWO PATIENTS HAVING primary malignant melanomatous meningiomas are presented. The symptomatology and clinical progress following surgery is described. These rare tumors seem uniformly resistive to cure by surgical or radiation therapy.

Melanomatous meningiomas are rare primary tumors which grow within or about the brain and spinal cord. Some of these tumors involve the meninges while others are intrinsic within the central nervous tissue. They are invasive and malignant, but do not seem to metastasize outside of the nervous system. Their histologic appearance has features of both meningioma and melanoma.

Normally melanin pigment granules occur in the pia mater of human adults and appear evident mostly over the ventral aspect of the lower medulla oblongata. Melanin containing cells may surround perforating vessels in areas of the brain which have pigmented leptomeninges constituting the appearance of melanosis. Such a condition is sometimes associated with cutaneous cafe-au-lait areas and is a benign condition.¹ Gibson, et al. in 1957 reviewed the problem of primary CNS melanomas and found 60 acceptable reported cases. In 1961, Kiel, et al.³ found in the literature a total of 86 valid melanomas of the central nervous system. The nature of these tumors have been amply described in other case reports also.⁴⁻¹⁰ These tumors occur during all ages of life with maximum prevalence in the fourth decade.²

Two case reports are presented here. The nature of, and the course of illness before and after treatment is quite typical for this type of tumor.

Case Reports

Case 1—41-year-old female.

History:

Onset of headaches, blurred vision and dizziness in September 1949 followed by left face and tongue numbness. Later there developed anorexia, weight loss and poor balance. Since 1940 the patient had experienced

Dr. Titrud practices in Minneapolis, Minnesota.

progressive left deafness and tinnitus. Recently the left arm and leg had become numb and the patient had become tired and weak.

Examination February 1950:

On neurologic examination there was horizontal nystagmus more prominent to the left but also vertical nystagmus. There was slight left peripheral facial weakness. Left air conduction hearing was absent and the left trigeminal divisions were hypesthetic. Additionally left arm hyperreflexia and ataxia existed.

The patient was hospitalized in March, 1950. Skull Xrays were normal. In the absence of papilloedema, a lumbar puncture obtained cerebrospinal fluid (CSF) containing 122 red blood cells, 66.2 mgm.% protein.

On 7 March, 1950, a left posterior craniotomy revealed no increase of intracranial pressure. In the left cerebellopontine angle there were large veins about the seventh and eighth cranial nerves where there was well

Fig. 1 (Case 1)—Low power photomicrograph shows the fibrous stroma of a meningioma with scattered pigment granules.

vascularized tissue extending into the cerebellar hemisphere. Much of this tissue was soft, necrotic and somewhat blue in color, suggestive of a hemorrhagic process. Eventually a 3 x 4 x 5 cm. tumor was removed without particular disturbance of the V, VII and VIII cranial nerves.

The pathologist found that this vascular tumor had relatively uniform cells with oval nuclei which stained moderately and were surrounded by an indefinite amount of granular cytoplasm. The vascular spaces had endothelial lining with the tumor cells resting on the endothelium. The tumor cells infiltrated into thickened tissue of a fibrous type resembling the meninges. There were dark brown irregular sized pigment granules scattered throughout the tumor. Special iron stains of this vascular tumor showed many deposits of iron-containing pigment, but there were fairly large deposits of a separate pigment which were free of iron. Mitotic figures were present but not numerous. The diagnosis was that of Meningeal Melanoma.

Postoperative radiation therapy was administered. In May, 1950, the patient developed tinnitus and recovery of hearing. There was almost no facial weakness. There was some left corneal and mandibular hypesthesia. The left upper extremity retained some ataxia and weakness.

In July 1955 the patient was hospitalized again. Her progress had been good, but over the past year she had become somewhat ataxic. There were no headaches. In June the patient had developed left face, ear, and suboccipital pain and neck stiffness together with nausea and vomiting.

Examination revealed mild neck rigidity. The left pupil was slightly dilated. Nystagmoid movements occurred in all directions. There was reduction of left hearing and left corneal sensation together with left facial weakness. The left arm and leg were ataxic and hyper-reflexia. There were bilateral Babinski toe signs. The patient improved with bed rest and returned home.

On December 12, 1955 the patient was again hospitalized. Her progress had been satisfactory until early December when she developed a severe headache and numbness over the entire body. Her speech was lost, right hemiplegia developed, and she became unconscious. The spinal fluid was found to be bloody. She expired on December 15, 1955. A complete autopsy was done. There was a large necrotic and hemorrhagic recurrent tumor in the left cerebello-pontine angle with brain stem compression. No other significant findings were found.

Case 2—74-year-old white male.

This man was hospitalized from 15 July until 30 July, 1971. He had developed some mental confusion and disorientation over the preceding two months. There had been two weeks of recent headache associated with visual blurring. Recent clumsiness of the left extremities had also occurred. Past health had been excellent.

Examination revealed the patient to be confused and disoriented. Physical and neurological examinations were normal. Electroencephalography was abnormal with diffuse slowing. A brain scan demonstrated increased activity in the posterior and inferior aspect of the right parietal area extending toward the midline. Carotid angiography revealed an area of relative avascularity in

Fig. 2 (Case 1)—High power demonstrates irregular cell formation and pigment granules.

Fig. 3 (Case 2)—Low power photomicrograph shows whorl formation and fibrous appearance of a meningioma.

he posterior and inferior distribution of the right middle cerebral branches. There was no vascular displacement.

A ventriculogram was carried out and the right brain cannula entered a cavity containing golden-yellow fluid that rapidly coagulated. A right parietal craniotomy revealed prominent increase of intracranial pressure. A large cavity was found adjacent to the lateral ventricle in the right parieto-occipital area containing what appeared to be clotted blood. These clots and necrotic tissue were removed providing a generous decompression. The post-operative course was gratifying. The patient was alert and was soon ambulatory. Hospital discharge was July 30th. No radiation therapy was administered.

Pathologic examination of the operative specimen demonstrated the hemorrhagic and necrotic tissue to have spindle shaped and cuboidal neoplastic cells. These malignant cells appeared to invade into the normal brain tissue and in these areas to contain an increased amount of pigment. The pigment was almost black and was distributed throughout the tumor in an irregular pattern. In some regions the cells seemed to form whorls along with areas of hemorrhage. The diagnosis was Malignant Meningioma, Melanomatous type.

This man returned to his local hospital 30 July, 1971 and appeared to get along quite well except for occasional fatigue, confusion and headache. In August, 1971, after a few hours of high fever, the patient suddenly expired. Unfortunately, no autopsy was done. Prior external medical examination of the patient had failed to reveal any tumor except the one involving the brain.

Summary

Two case reports of melanomatous meningiomas are added to the relatively few reported in the literature. One of these tumors was deep within the brain adjacent to the lateral ventricle which is a very uncommon location for a meningioma. Neither surgical or radiation treatment appears to

halt the course of these tumors. Additionally Williams⁸ reported the unsuccessful use of vincristine in a case of this sort. It is hoped that some form of chemotherapy may become available for all malignant brain and spinal cord tumors.

Fig. 4 (Case 2)—High power photomicrograph demonstrates pigment granules among the spindle cells of the tumor.

Postgraduate Course on the Small Intestine and Colon

Third annual course in Gastroenterology will be presented by the Graduate Medical Education Department of the Alton Ochsner Medical Foundation with distinguished faculty of visiting professors, local area guests and the staff of the Ochsner Medical Center at the Ochsner Medical Center, February 1, 2, 3, 1973.

Consideration is given this year to disease problems of the small bowel and colon with approach from the standpoint of newer developments in the patho-physiologic processes of these conditions.

Inquiries concerning this course should be directed to: William H. McFarland, Administrator, Alton Ochsner Medical Foundation, Graduate Medical Education Department, 1514 Jefferson Highway, New Orleans, Louisiana 70121.

Acute Perforating Diverticulitis

Emergency Surgical Treatment

PETER ENDREY-WALDER, M.B., B.S. AND EDWARD S. JUDD, M.D.

IN RECENT YEARS, steady progress has been made toward establishing principles in the surgery of chronic or recurrent diverticulitis of the colon,^{1,2} which in the elective cases has resulted in satisfactory morbidity and mortality rates.³ Occasionally the surgeon is confronted with an acute problem for which time does not permit the orderly, complete preparation of the colon and the patient. In the acute situation the surgeon must decide among several possibilities, each with a known risk factor. If a frank abscess is present, drainage is mandatory and a proximal colostomy is the accepted procedure. If the perforated bowel can be mobilized, several choices are available: (1) an obstructive or extraperitoneal resection (a modification of the earlier exteriorization operation) may be done; (2) the lesion may be resected, the rectosigmoid being closed as a stump and a temporary single-barrel colostomy being carried out with the proximal colon for later reestablishment of continuity (Hartmann method); (3) the lesion may be resected and the end-to-end anastomosis protected with a temporary proximal colostomy; (4) a primary resection and immediate anastomosis without colostomy may be done.

Because we had no current information of our results with surgical management of this acute problem, we analyzed our experience over a recent decade.

Material

Our material was selected from the records of 775 patients who had undergone surgery for diverticular disease of the colon during the 10-year period between 1961 and 1970. There were two criteria for inclusion in the series: (1) The surgical procedure was an emergency (this excluded any planned work-up, bowel preparation, etc., but not

immediate preoperative resuscitation) and (2) there was evidence of perforation, either as a recognized defect in the colon wall at operation or as a pericolic or mesocolic abscess (as a consequence of acute diverticulitis) on examination of the excised specimen.

Fifty-four cases met these criteria: there were 27 men, with an average age of 57 years (range 42 to 84 years) and 27 women, with an average age of 61 years (range 31 to 83 years).

Preoperative Condition of Patients

The degree of surgical risk immediately before operation was used to classify the patients. Because classification was done retrospectively, it was based on such parameters as chronologic age, concurrent diseases, or medications (for example, steroid treatment) as well as on data, such as blood pressure readings, pulse rate, estimated degree of dehydration, and electrocardiographic findings.

Only one patient was in poor enough condition to have been refused a general anesthetic, and he was the only one classified as a very bad risk. The condition of 20 patients was poor because of advanced ischemic heart disease, severe diabetes, prolonged high dosage steroid treatment, other severe concurrent diseases, and advanced peritoneal infection; these patients made up 40% of the series.

The duration of acute symptoms or of symptoms whose severity had gradually increased to a maximum, necessitating surgical intervention, averaged four days. Patients who died during their initial hospitalization suffered from such

TABLE 1
Preoperative Risk and Mortality in 54 Cases of
Emergency Acute Perforating Diverticulitis

Very bad	1	1	100
Moderately bad	20	8	40
Good	33	2	6
Total	54	11	20

Mayo Clinic and Mayo Foundation, Rochester, Minnesota.
Read at the meeting of the Minnesota Surgical Society, Rochester, Minnesota, May 5, 1972.

symptoms for an average of seven days and had more advanced local or generalized peritoneal involvement.

The relationship of preoperative risk to mortality is shown in Table 1.

Operative Findings

Although the operative findings were difficult to compare, there were two basically different groups of patients: (1) those with apparently localized changes in the pericolic or mesocolic region and (2) those with generalized peritonitis or distal abscesses. Because generalized peritonitis is not in itself a surgically treatable condition, and because the mortality rate was only 3.8% (one patient) when the infection was localized, as compared to a rate of 35.6% when it was not, there was no decisive preference for any of the various forms of standard surgical management.

The relationship of findings at surgery to mortality is shown in Table 2.

TABLE 2
Findings at Laparotomy and Mortality in
54 Cases of Emergency Acute Perforating
Diverticulitis

Finding	No. of patients	Deaths No.	%
Generalized peritonitis	28	10	35.6
Pericolic and/or mesocolic abscess	26	1	3.8
Total	54	11	20.4

Surgical Procedures

The results of the operative procedures in the two groups of patients were analyzed (Table 3). When generalized peritonitis was present, the mortality rates were similar when the various resective measures were compared with the simpler colostomy and drainage. This was also true when the changes were localized. None of the 19 patients who underwent defunctioning colostomy or drainage (or both) developed overwhelming peritonitis. The combination of diversion of feces, draining localized abscess, antibiotics, and other supportive measures seemed to prevent further spread of infection.

Analysis of Mortality

Eleven of the 54 patients died (Table 4). Ten of the 11 had generalized peritonitis at laparotomy, and this contributed significantly to the deaths of nine. Two patients (Cases 4 and 5) were extremely ill; one (Case 4) had survived three episodes of

rejection of a renal transplant in the previous six months. He was treated with high doses of immunosuppressants as well as steroids. The other (Case 5) was responding slowly to splenectomy that had been performed two weeks earlier for the acute hemolytic crisis of systemic lupus erythematosus. Significantly, eight of the nine patients who were receiving cortisone had generalized peritonitis, and six of these died. Peritonitis was the most important prognostic factor. All but one of the patients who were on steroid medication had peritonitis. A significantly higher average age (66 years for those who died as opposed to 57 years for those who survived) was also a poor prognostic feature.

Causes of Death and Nature of Complications

Uncontrollable infection was an important cause of death; however, most of those who died had many contributing conditions (Table 5).

Of the postoperative complications, wound infection was the most frequent, afflicting 23 (42%) patients (Table 6). Most of the wounds were closed primarily; possibly initial packing of the wound, followed by secondary closure, might have reduced the percentage of infection.

Fecal fistulas developed in four patients: one each after transverse defunctioning colostomy plus drainage, after sigmoid resection with defunctioning colostomy, after left hemicolectomy, and after sigmoid resection without colostomy (the last two eventually were self-healing). Thus this complica-

Resection	15	15

*Between emergency surgery and final dismissal.

tion developed after only one of the 41 nonresective operations, but after three of the 11 resections with primary anastomosis.

Morbidity

Hospital morbidity data (Table 7) did not include the 11 patients who died during the initial hospitalization, two patients who died prior to completion of further surgery, three patients who declined further treatment, and two patients who were lost to follow-up; all of these 18 patients had some form of defunctioning colostomy and drainage.

The two patients who died prior to resection and closure of the colostomy died in the interval period from causes other than diverticular disease, and none of those who later underwent definitive surgery died as a consequence of such an operation.

Summary

From 1961 to 1970, 775 patients underwent surgical treatment for diverticular disease of the colon. Only 54 of these underwent emergency surgical treatment, which precluded any planned preparation of the colon. All 54 had evidence of a perforated colon. For those in the good-risk category, the hospital mortality was much lower. If general peritonitis was present, the mortality rate was 35.6%. If the infection was localized, the rate was 3.8%. Various surgical procedures were employed, but none was superior.

Significant contributing factors to mortality were the use of steroids and advanced age (average 66 years). The leading complication was wound infection. Packing the wound, with delayed closure, is worth considering.

Duplay's Syndrome

This commonly observed calcifying tendinitis or peritendinitis involving the shoulder area constitutes one of the etiologic components of the supraspinatus syndrome. It was first described by Duplay (1896) as "scapulohumeral periarthrititis."

Cardinal symptoms consist of pain and limitation of motion of the shoulder joint. Calcification is frequently present in both shoulders and may long be asymptomatic. When pain does occur, it may be quite intense and often prevents sleep despite generous doses of narcotics. Three varieties of "frozen shoulder" have been described: (1) a localized form with general articular involvement, in persons under 40 years of age; (2) a degenerative form, in persons over 40 years of age; and (3) a posttraumatic form from a tear in the rotation cuff.

One theory concerning cause of the calcium deposition includes occlusion of the vessels of the tendon from hypertrophy of the tunica media. As in aseptic necrosis of the head of the humerus or elsewhere, local necrosis of the tissues occurs, followed by the deposition of calcium. Almost immediate relief may be obtained by opening the tendon capsule surgically. Many cases will respond promptly to the local injection of an anesthetic agent, as procaine and hydrocortisone. Irradiation of the area also affords gradual relief of pain and, in many instances, complete disappearance of the calcific deposit within a few months.

Colistin Toxicity

Neuromuscular and Renal Manifestations

Two Cases Treated by Hemodialysis

DONALD A. DUNCAN, M.D.

EARLY STUDIES SUGGESTED that colistin (polymixin E), a polypeptide antibiotic isolated from the soil organism *Aerobacillus colistinus*, was relatively non-toxic, especially when compared to polymixin B.^{1,2} Subsequent experience has revealed a high incidence of both neurotoxicity and nephrotoxicity.^{3,4} Neurotoxic manifestations have ranged from mild paresthesias to a generalized neuromuscular blockade resulting in quadriplegia and apnea.^{3,5} Nephrotoxic reactions have included the production of proteinuria, hematuria or cylindruria, impairment of renal concentrating ability, development of non-oliguric renal insufficiency with progressive azotemia, and acute tubular necrosis.^{4,6,7} It now appears that when colistin and polymixin B are given in doses of equal antibacterial effectiveness, their toxicity is similar.⁸

Two patients treated in the Methodist Hospital (Minneapolis, Minnesota) Hemodialysis Center for adverse reactions to colistin are presented to illustrate many aspects of colistin-induced neurotoxicity and nephrotoxicity as well as the effect of hemodialysis on serum concentrations of the drug. Both patients received colistin intramuscularly as the methane sulfonate derivative, sodium colistimethate (Coly-mycin®M). Case 1 received approximately six times the usually recommended dose while Case 2 received an appropriate dose. Neither had evidence of renal disease before colistin was administered.

Materials and Methods

Serum samples from Case 1 were assayed for colistin by a cylinder plate method in which *Bordetella bronchiseptica* A.T.C.C. 4617 was used as

the test organism.* Inhibition of bacterial growth by the patient's serum was compared to that produced by known concentrations of colistin base. Results are reported as micrograms of colistin base activity per milliliter of serum tested.

One patient was dialyzed 10 hours with two Cordis-Dow† hollow fiber (capillary) dialyzers arranged in series (Figure 1) to reduce the concentration of colistin in her blood. Each dialyzer received dialysate from an individual Milton-Roy‡ single-pass delivery system at 500 ml/min. Other dialyses for the control of uremia in both patients

Fig. 1 (Case 1)—Two Cordis-Dow capillary dialyzers arranged in series to produce a highly efficient hemodialysis system. Each dialyzer is perfused by a separate dialysate supply system.

were performed with either the Ultra-Flo 145 twin coil dialyzer in conjunction with the Travenol RSP* dialysate delivery unit or a modified two-layer Kiil dialyzer attached to the Milton-Roy single-pass delivery system. These dialyses were of six to eight hours duration.

Case Reports

Case 1

A 16-year-old girl weighing 45 kg. was hospitalized elsewhere on July 8, 1971, with acute appendicitis. Urinalysis was normal with specific gravity 1.029. Appendectomy revealed evidence of early perforation. *Escherichia coli* sensitive to colistin, chloramphenicol, nitrofurantoin and streptomycin was cultured from the periappendiceal area. Therapy with colistin and chloramphenicol was started on July 10.

Chloramphenicol was discontinued after a total of 1750 mg. Four injections of 150 mg colistin were given on July 10 at four-hour intervals. The next day six more injections of 150 mg each were given. Over a period of 40 hours the patient received 1500 mg, equivalent to 900 mg/24 hours or 20 mg/kg/day.

By noon, July 11, the patient complained of dizziness when standing. At 7:00 P.M., she exhibited generalized weakness and had difficulty walking. About midnight apprehension and respiratory distress developed. Respirations were shallow at 28/min. By 12:30 A.M., July 12, she was apneic. Resuscitative measures were initiated but cardiac arrest ensued. The pupils dilated and became non-reactive. An endotracheal tube was inserted and external cardiac massage administered for approximately 30 minutes before a regular sinus rhythm was restored. Continuous ventilatory assistance was maintained with a positive-pressure respirator. Colistin was discontinued. Several hours later her condition deteriorated and she was transferred to Methodist Hospital.

Examination at noon, July 12, revealed a deeply comatose, apneic, noncyanotic young girl who required continuous artificial ventilation. Pupils were dilated and non-reactive. There was a flaccid quadriplegia, absence of corneal and deep tendon reflexes, no Babinski reflex and no response to noxious stimuli. The pulse was 120, blood pressure 90/70 mm Hg, and temperature 39.6°. Moist inspiratory rales were audible throughout the left lung. The abdomen was soft with a Penrose drain in the appendectomy incision.

The WBC was 21,600/mm³ with 97% neutrophils. Urinalysis showed 3+ protein, 5 WBC and 15 RBC per high-power field and many granular casts. Hemoglobin was 14.1 g/100 ml, blood urea nitrogen 23 mg/100 ml, sodium 133 mEq, potassium 5.2 mEq, chloride 108 mEq and CO₂ content 14.4 mEq/liter. Chest Xray showed an extensive infiltrate throughout the left lung compatible with an aspiration pneumonia. An initial sputum culture was negative but *Proteus* and *Enterobacter* species were cultured four days later. An electroencephalogram revealed bilateral diffuse slow-wave activity with left frontal-temporal spike foci. The urine volume

averaged only 24 ml/hour prior to the administration of furosemide.

The pneumonia was treated with chloramphenicol, ampicillin and dexamethasone. The hospital course over the next few days was as follows (also see Figure 2 where Day 1 corresponds to July 12, 1971):

July 12, 1971

5:00 P.M.—Occasional spontaneous movements of the hands.

July 13, 1971

6:00 A.M.—Opened eyes on command.

10:00 A.M.—Moved extremities on command. Apneic, pupils dilated, but deep tendon reflexes returning. Urine volume fixed at 50 ml/hour despite 1000 mg furosemide/24 hours in divided doses. Creatinine clearance 1.3 ml/min/1.73m².

11:00 A.M.—Start 10-hour hemodialysis with two capillary dialyzers to remove colistin.

6:00 P.M.—Intermittent spontaneous respirations. Able to speak a few words.

July 14, 1971

8:00 A.M.—Mentally alert. Cyanotic with shallow respirations when artificial ventilation withheld. Altered blood coming from nasogastric tube.

Noon—Respirator discontinued and endotracheal tube removed.

On July 16 hemoptysis without pleuritic pain developed. Two days later tenderness and swelling of the left calf appeared, then gradually subsided following treatment with heat and elevation. By July 19 the chest Xray was normal.

Hemodialyses were performed on July 17 (Day 6, Figure 2) and July 22 to control uremia. Increased upper gastrointestinal hemorrhage occurred on July 23. Subsequent Xray of the stomach and duodenum was normal. The bleeding was believed to be due to uremic gastritis. A final dialysis was performed July 24. A repeat electro-

Fig. 2 (Case 1)—Hospital course of patient beginning with onset of apnea after receiving colistin, 150 mg every four hours times 10 doses during the preceding two days. D indicates dialysis. The first dialysis was to remove colistin, the other three to control symptoms of uremia. Relatively large amounts of furosemide produced only a mild but sustained diuresis.

*Travenol Laboratories, Inc., Morton Grove, Illinois.

encephalogram July 26 was normal. By July 30 urinalysis was normal except for a few granular casts. Creatinine clearance was 25 ml/min/1.73 m².

The patient returned to school in September with no obvious mental impairment. An intravenous pyelogram was normal. Creatinine clearance was up to 60 ml/min/1.73 m² by October 28. Extensive psychological testing in November failed to reveal any evidence of neurological dysfunction. On intelligence testing* the patient obtained a verbal IQ of 109, a performance IQ of 108 and an overall full-scale IQ of 109.

Now, eight months following the renal injury, urinalysis is normal with a random specific gravity 1.020, blood urea nitrogen 15 mg/100 ml, serum creatinine 0.9 mg/100 ml and creatinine clearance 71 ml/min/1.73m₂.

Case 2

A 23-year-old woman weighing 60 kg, was hospitalized December 21, 1968, with compound comminuted fractures of the left tibia and fibula incurred in an automobile accident. The wound was debrided, screws inserted and a cast applied. Admission urinalysis was normal with specific gravity 1.018. One week later the fracture site appeared infected. A culture produced *Pseudomonas aeruginosa* sensitive to colistin.

On January 3, 1969, 180 mg (3 mg/kg) colistin was administered in divided doses. On January 4, 5 and 6 the total daily dose given was 240, 180 and 120 mg respectively. Circumoral and acral paresthesias developed on January 5 and progressed the next day, after which the colistin was discontinued.

The daily urine volume since admission exceeded 1500 ml and remained high at 2700 ml on January 6. On this date the blood urea nitrogen was 17 mg/100 ml. Then on January 7 the paresthesias improved but the patient complained of nausea and was noted to be almost totally anuric. Thirty g mannitol intravenously failed to improve renal function. The total 24-hour urine volume was 25 ml.

The patient's subsequent course is shown in Figure 3 where Day 1 corresponds to January 3. Hemodialyses to control symptomatic uremia were performed on Day 8 when the blood urea nitrogen reached 95 mg/100 ml and again on Day 11. After six days of oliguria diuresis began. By January 24 (Day 22) the blood urea nitrogen returned to normal. The fracture site healed slowly after additional debridement and application of skin grafts.

Three years later, January 1972, urinalysis was normal with specific gravity 1.024, blood urea nitrogen 12 mg/100 ml, serum creatinine 0.8 mg/100 ml and creatinine clearance 68 ml/min/1.73 m².

Results

The creatinine clearance of the two hollow fiber dialyzers arranged as shown in Figure 1 was 119 ml/min (115 and 122 ml/min on two determinations) and the urea clearance 155 ml/min (148 and 162 ml/min on two determinations) at a blood flow of 200 ml/min. Under similar conditions the creatinine and urea clearances for a

single hollow fiber dialyzer were found to be 98 and 125 ml/min respectively. Figure 4 shows the effect of dialysis on the serum colistin concentration of Case 1. The rate of fall was greater during the period of dialysis—hours four to 14—than before or after. During the 10 hours of dialysis the serum colistin concentration fell 0.4 mcg/ml/hr compared to 0.044 mcg/ml/hr during the 34 hours post-dialysis. These results suggest that colistin was removed by hemodialysis under the conditions of the present study.

Patient one received four to eight times the recommended dose of 2.5 to 5.0 mg/kg/day of colistin.⁹ Acute renal failure and neuromuscular paralysis manifested by generalized weakness, difficulty walking, apnea and a flaccid quadriplegia resulted. Hypoxic cerebral injury due to the cardio-respiratory arrest may have contributed to the quadriplegia. The serum colistin concentration at

Fig. 3 (Case 2)—Hospital course of patient, beginning with the administration of colistin. Oliguria developed suddenly on Day five and was associated with rapidly progressive azotemia.

Fig. 4 (Case 1)—Concentration of colistin in the serum of patient before, during and after hemodialysis with the two capillary dialyzers. Time "0 Hours" when the serum colistin concentration first was measured, was 7:00 A.M., July 13, 1971, 31 hours following onset of apnea, and 33 hours after the last injection of colistin.

*Wexler Adult Intelligence Scale.

the time apnea first developed is not known, for the concentration of 10 mcg/ml at time 0 hours in Figure 4 was not obtained until 31 hours later. Despite dialysis 84 hours elapsed following onset of apnea before respiratory function returned completely to normal.

The renal failure of Case 1 was converted from oliguric to nonoliguric by the administration of furosemide. However, despite a urine volume of greater than 1000 ml/day, the blood urea nitrogen and serum creatinine rapidly rose, requiring additional dialyses.

Case 2 developed circumoral and acral paresthesias as the only neurotoxic symptoms. These disappeared 48 to 72 hours after the colistin was stopped. Both patients recovered completely from the neurotoxicity, but creatinine clearances eight and 36 months later were borderline low.

Discussion

Colistin is excreted by the kidneys and the incidence of nephrotoxicity is high. Koch-Weser, et al., detected development of renal insufficiency in 20% of 317 courses of colistin therapy.⁴ Acute tubular necrosis occurred in another 1.9%. Some reports suggest that nephrotoxicity is dose related and occurs only when colistin is given in excessive amounts or to persons with pre-existing renal disease.^{10,11} Case 2, who received 2 to 4 mg/kg/day, and some of the cases of Koch-Weser, et al.,⁴ indicate that therapeutically recommended amounts given to persons without antecedent renal disease also can produce acute renal failure.

Evidence of nephrotoxicity usually occurs during the first two to four days of therapy and may continue to progress after the colistin has been discontinued.⁴ Microscopically the kidneys may show no recognizable pathology¹² or may show evidence of acute tubular injury, including necrosis.^{6,7,11,13} If the patient survives the period of acute oliguric renal failure subsequent recovery may be complete¹³ or marginal (Cases 1 and 2).

Neurotoxicity has been reported to occur in over 7% of patients treated with colistin, with respiratory insufficiency or apnea in 2%.⁴ Apnea may not be preceded by lesser neurotoxic symptoms such as paresthesias.

Aminoglycoside antibiotics such as neomycin, streptomycin and kanamycin as well as the polymyxins are capable of producing an acute neuromuscular blockade.^{3,14} The clinical syndrome produced resembles myasthenia gravis with apnea

being due to respiratory muscle paralysis and not due to central nervous system toxicity. Although such reactions have occurred in patients with known myasthenia gravis,^{14,15} most affected persons do not have this disorder. The polymyxins have a greater propensity to produce a neuromuscular blockade than do other antibiotics.

The mechanism of the neuromuscular blockade is not the same for all antibiotics. For example, studies in rats suggest that at the myoneural endplate neomycin interferes with acetylcholine release from the nerve ending and reduces sensitivity of the postjunctional membrane to acetylcholine.^{14,16} The latter effect resembles that induced by curare. Colistin and polymixin B appear to have a presynaptic effect only, probably interfering with the release of acetylcholine.^{14,16}

It is tempting to relate the action of colistin on the nerve cell to its action on bacteria. The polymyxins are thought to produce their antibacterial effect by acting as cationic detergents that bind to anionic sites on the lipid-rich bacterial cell membrane, thereby disrupting it.^{17,18} They may attack lipid-rich neurons similarly.

Relatively small amounts of the polymyxins can produce the neuromuscular blockade. Lindesmith, et al.,³ described a patient who developed apnea less than two hours after receiving a single 50 mg injection of polymixin B. Muscle weakness without apnea has been reported to occur with a blood concentration of colistin as low as 2 mcg/ml.⁵ The desired therapeutic level is probably in the range of 5 to 8 mcg/ml.^{5,12,19} Koch-Weser et al. found that 83% of neurotoxic reactions occurred before a total of 1 g colistin was given.⁴

Management of the neuromuscular blockade consists of discontinuing the colistin and supporting respiration. Administration of neostigmine or edrophonium (Tensilon^R) with perhaps rare exceptions⁵ is of no benefit.³ Although the mechanism is uncertain, intravenous calcium has seemed beneficial in occasional cases.³ The calcium may act by enhancing the release of acetylcholine.¹⁴ As the colistin is eliminated from the body, recovery from the neuromuscular blockade is complete.³ Dialysis would seem indicated only when acute renal failure markedly impairs the ability of the patient to excrete the drug.

Colistin is not easily removed by dialysis. Neither Goodwin and Friedman¹⁹ nor MacKay and Kaye²⁰ could demonstrate removal by hemodialysis using the Kolff twin coil dialyzer which has a

urea clearance of approximately 120 ml/min at a blood flow of 200 ml/min.²¹ Likewise Goodwin and Friedman could not lower the serum concentration of colistin using a modified two-layer Kiil dialyzer. Gombos, et al.,²² using the same Kiil dialyzer (urea clearance 82 ml/min, creatinine clearance 62 ml/min at a blood flow of 200 ml/min) claim to have demonstrated removal of colistin. Dialyzed patients had a decrease in serum colistin concentration of from 57 to 66% as compared to 33 to 57% for controls. However, the dialyzed patients were followed for 10 hours and the controls only six to eight hours. Recalculating their results at the six-hour period reveals an average decrease of 51% (seven patients, range 40 to 61%) for the dialyzed patients, compared to an average decrease of 40% (three patients, range 27 to 57%) without dialysis. The difference is not very impressive.

Curtis and Eastwood,²³ also using the Kiil dialyzer with a single-pass dialysate flow, demonstrated that the serum colistin concentration fell an average of 1.16 mcg/ml/hr during dialysis of three patients as compared to a decrease of 0.36 mcg/ml/hr without dialysis. Although the rate of fall in Case 1 during dialysis was less than that obtained by Curtis and Eastwood,²³ perhaps due to greater tissue and protein binding as a result of the long period between administration

and dialysis, the highly efficient hemodialysis system used resulted in a decrease that was greater during dialysis than after.

There is some evidence that colistin can be removed by peritoneal dialysis, but the amount is small.^{19,24}

Summary

Two patients who developed neurotoxic and nephrotoxic reactions from colistin are described. Neither had previous evidence of renal disease. One patient developed acute renal failure and a neuromuscular blockade that resulted in quadriplegia, apnea and cardiac arrest after receiving an excessive amount of the drug (20 mg/kg/day). The other developed paresthesias and acute renal failure following an appropriate dose of colistin (2 to 4 mg/kg/day for four days). Both patients required hemodialysis but subsequently recovered completely except for a marginal impairment of renal function as measured by the creatinine clearance.

The results of serum assays suggest that by using two Cordis-Dow hollow fiber dialyzers arranged in series with a single-pass dialysate delivery system colistin was removed by hemodialysis from the patient who received the larger amount.

A Pedunculated Cyst of the Heart

J. R. HASTINGS, M.D. AND W. R. ANDERSON, M.D.

CARDIAC EPITHELIAL cysts of endodermal origin are uncommon in the world literature. This report presents a posterior left ventricular cyst of probable endodermal origin.

Case Report

A 19-year-old-Caucasian male was involved in a single car accident, sustaining severe closed-head trauma. He expired, six hours after the accident, of cerebral edema and uncal herniation. Past history was unremarkable though there was an alleged history of drug abuse.

At autopsy, in addition to diffuse cerebral injuries and several fractured ribs, there was a spherical 7 mm cyst fixed to the posterior lateral ventricular wall adjacent to the chordae tendineae of the posterior papillary muscle and arising between trabeculae carneae (see Figure 1). This cyst was yellow-white in color, relatively soft, and of an apparent homogenous consistency. It was pedunculated with a one mm stalk that was composed of myocardial tissue.

Microscopically the outer surface of the cyst was composed of cells that were continuous with those of

the endocardium. There was a second layer of underlying cells and these were ciliated, columnar and closely resembled cells lining the respiratory passages. The cyst was filled with an amorphous, acellular eosinophilic coagulum (see Figure 2). Elastin, reticulum, P.A.S. and mucin stains were negative.

Comment

Epithelial cysts have been found in numerous locations within the heart, but there is only one other reported case of a pedunculated cyst.¹⁰ In the other instances of epithelial cysts, the lesion rarely projected above the endocardial surface.

Generally, the cysts fall into two patterns, ciliated and non-ciliated, with the former found more commonly in the left ventricle and the latter in the right atrium.⁶ Although the cysts have all been reported as incidental findings, they potentially could serve as a nidus for thrombus formation, cause conduction defects or, if the stalk ruptured, cause a lethal embolus. Table 1 summarizes the epithelial cysts of the heart which have

From the Pathology Department of Hennepin County General Hospital.

13	Rabson	29	F	? RHD and Stokes Adams Syndrome	Microscopic	Posterior wall, left atrium and A.V. sulcus	Cuboidal
9	Leighton	58	F	Cerebral embolus	16 x 10 x 9	Left ventricular lat. wall below A.V. sulcus	Columnar, ciliated
2	Brandt	6 mo.	F	Pneumonia, cong. heart disease	2.5 x 2 x 1.5	Interatrial septum	Stratified squamous
5	Epstein	73	F	Mitral insufficiency	Cherry-sized	Left ventricle, posterior wall	—
10	Marshall	30	M	Multiple brain tumors	5 x 4 x 4	Left ventricle, post. wall pedunculated	Pseudostratified ciliated, one layer columnar, ciliated
11	Morris	86	F	Cerebral ischemia Cardiac cond. defect	20 x 10 x 10	A-V septum	—
	Hastings	19	M	Closed head trauma	7 mm. in diameter	Left ventricle, post. wall pedunculated	Two layers, flat cuboidal, inner layer columnar, ciliated

been reported.

Several theories have been advanced to describe the origin and occurrence of these lesions: (1) Anomalous differentiation of cardiac mesoderm, (2) Origin in dermoid cysts, (3) Epicardial malformations, (4) Displacement of postbranchial body tissue, and (5) Sequestration of respiratory epithelium.¹⁰

The sequestration of respiratory epithelium seems best able to explain the formation of cysts similar to that reported here. The cardiovascular system and respiratory system are both formed at approximately the same embryological time. The

primordium of the respiratory system arises from the ventral surface of the foregut at about 21 days. Immediately ventral to these structures, the primitive endocardial heart tubes fuse, forming a single endocardial tube.⁸ It is entirely possible that entrapment of primitive respiratory epithelium may occur within the developing myocardium at this stage. The pedunculation of the cyst described here is unusual but could occur if the structure lay within the myocardium at one stage of its development and then was extruded to the surface as the left ventricle continued to develop.

"Are you a doctor?" He turned his fierce dark eyes upon me as he asked this last question.

"Yes, I am," I answered.

"Then put your hand here," he said, with a smile, motioning with his manacled wrists towards his chest.

I did so; and became at once conscious of an extraordinary throbbing and commotion which was going on inside. The walls of his chest seemed to thrill and quiver as a frail building would do inside when some powerful engine was at work. In the silence of the room I could hear a dull humming and buzzing noise which proceeded from the same source.

"Why," I cried, "you have an aortic aneurism!"*

EMPIRIN[®] COMPOUND c CODEINE

#3, codeine phosphate* (32.4 mg.) gr. ½
#4, codeine phosphate* (64.8 mg.) gr. 1

IMPORTANT INFORMATION: This is a Schedule V substance by Federal law; diphenoxylate HCl is chemically related to meperidine. In case of overdosage or individual hypersensitivity, reactions similar to those after meperidine or morphine overdosage may occur; treatment is similar to that for meperidine or morphine intoxication (prolonged and careful monitoring). Respiratory depression may recur in spite of an initial response to Nalline® (nalorphine HCl) or may be evidenced as late as 30 hours after ingestion. LOMOTIL IS NOT AN INNOCUOUS DRUG AND DOSAGE RECOMMENDATIONS SHOULD BE STRICTLY ADHERED TO, ESPECIALLY IN CHILDREN. THIS MEDICATION SHOULD BE KEPT OUT OF REACH OF CHILDREN.

Indications: Lomotil is effective as adjunctive therapy in the management of diarrhea.

Contraindications: In children less than 2 years, due to the decreased safety margin in younger age groups, and in patients who are jaundiced or hypersensitive to diphenoxylate HCl or atropine.

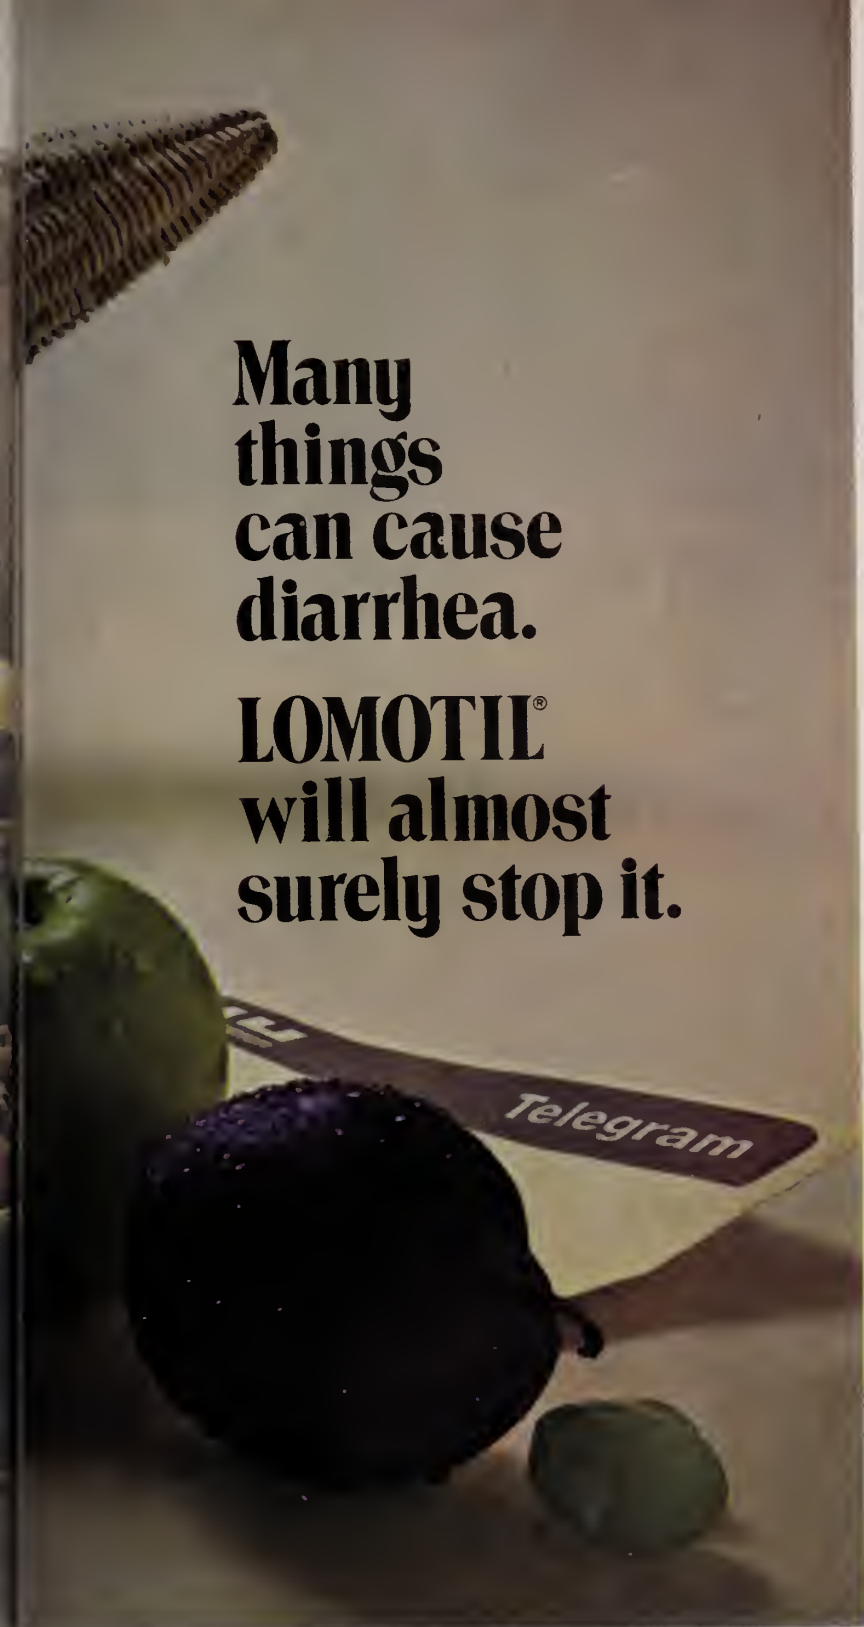

Warnings: Use with caution in young children, because of variable response, and with extreme caution in patients with cirrhosis and other advanced hepatic disease or abnormal liver function tests, because of possible hepatic coma. Diphenoxylate HCl may potentiate the action of barbiturates, tranquilizers and alcohol. In theory, the concurrent use with monoamine oxidase inhibitors could precipitate hypertensive crisis.

Usage in pregnancy: Weigh the potential benefits against possible risks before using during pregnancy, lactation or in women of childbearing age. Diphenoxylate HCl and atropine are secreted in the

breast milk of nursing mothers.

Precautions: Addiction (dependency) to diphenoxylate HCl is theoretically possible at high dosage. Do not exceed recommended dosages. Administer with caution to patients receiving addicting drugs or known to be addiction prone or having a history of drug abuse. The subtherapeutic amount of atropine is added to discourage deliberate overdosage; strictly observe contraindications, warnings and precautions for atropine; use with caution in children since signs of atropinism may occur even with the recommended dosage.

Adverse reactions: Atropine effects include dryness of skin and mucous membranes, flushing and urinary retention. Other side effects with Lomotil include nausea, sedation, vomiting, swelling of the gums, abdominal discomfort, respiratory depression, numbness of the extremities, headache, dizziness, depression, malaise, drowsiness, coma, lethargy.

**Many
things
can cause
diarrhea.**

**LOMOTIL®
will almost
surely stop it.**

The causes of diarrhea are as varied as man's complaints and indiscretions. Because the causes of diarrhea can be obscure and because uncontrolled diarrhea can present serious problems, it is important to know a drug that will usually stop diarrhea promptly. For many physicians, the antidiarrheal drug of choice is Lomotil. It provides almost certain control of diarrhea.

It is also useful in controlling the intestinal transit time of patients with ileostomies and colostomies and the diarrhea occurring after gastric surgery.

Serious side effects are infrequent with Lomotil. It should be used with caution in young children, however, because of their variability in response. Use of Lomotil in children under two years of age is contraindicated.

**For the almost certain
control of diarrhea,**

LOMOTIL®

TABLETS/LIQUID

Each tablet and each 5 ml. of liquid contain:
Diphenoxylate hydrochloride 2.5 mg.
(Warning: may be habit forming)
Atropine sulfate 0.025 mg.

SEARLE

SEARLE & CO.
San Juan, Puerto Rico 00936

Address medical inquiries to:
G. D. Searle & Co., Medical Department
Box 5110, Chicago, Illinois 60680

nausea, restlessness, euphoria, pruritus, angioneurotic edema, giant urticaria and paralytic ileus.

Dosage and administration: *Lomotil is contraindicated in children less than 2 years old.* Use only liquid for children 2 to 12 years old. For 2 to 5 years, 4 ml. (2 mg.) t.i.d.; 5 to 8 years, 2 mg. q.i.d.; 8 to 12 years, 4 ml. (2 mg.) 5 mg. daily; adults, two tablets (5 mg.) t.i.d. to two tablets (5 mg.) q.i.d. or two regular teaspoonfuls (10 mg.) q.i.d. Maintenance dosage may be as low as one fourth of the initial dosage. Make downward dosage adjustment as soon as initial symptoms are controlled.

Dosage: Keep the medication out of the reach of children since accidental overdose may cause drowsiness, even fatal, respiratory depression. Signs of overdose include flushing, lethargy or coma, hyporeflexes, nystagmus, pinpoint pupils, tachycardia and respiratory depression which may occur

12 to 30 hours after overdose. Evacuate stomach by lavage, establish a patent airway and, when necessary, assist respiration mechanically. Use a narcotic antagonist in severe respiratory depression. Observation should extend over at least 48 hours.

Dosage forms: *Tablets*, 2.5 mg. of diphenoxylate HCl with 0.025 mg. of atropine sulfate. *Liquid*, 2.5 mg. of diphenoxylate HCl and 0.025 mg. of atropine sulfate per 5 ml. A plastic dropper calibrated in increments of ½ ml. (total capacity, 2 ml.) accompanies each 2-oz. bottle of Lomotil liquid.

Dosage forms: *Tablets*, 2.5 mg. of diphenoxylate HCl with 0.025 mg. of atropine sulfate. *Liquid*, 2.5 mg. of diphenoxylate HCl and 0.025 mg. of atropine sulfate per 5 ml. A plastic dropper calibrated in increments of ½ ml. (total capacity, 2 ml.) accompanies each 2-oz. bottle of Lomotil liquid.

MINOCIN® made the difference in just eight days.*

Clinical Data:

Patient: 47-year-old male.

Diagnosis: Severe pyoderma, left hand.

Culture: *Staphylococcus aureus*, coagulase positive and sensitive to MINOCIN.

Temperature: 102° F

Therapy: MINOCIN Minocycline HCl Capsules, 100 mg: 200 mg *stat*, 100 mg every 12 hours. Medication began 9/7/71. By fourth day, temperature was normal and pustular lesions considerably improved. Last dose taken 9/14/71.

Concomitant therapy: None.†

Semisynthetic

MINOCIN®
MINOCYCLINE HCl

Capsules, 100 mg: 2 *stat*, 1 q 12 h.

Minocycline is a tetracycline with activity against a wide range of gram-negative and gram-positive organisms.

Contraindications: Hypersensitivity to any tetracycline.

Warnings: The use of tetracyclines during tooth development (last half of pregnancy, infancy and childhood to the age of 8 years) may cause permanent discoloration of the teeth (yellow-gray-brown). This is more common during long-term use but has been observed following repeated short-term courses. Enamel hypoplasia has also been reported. Tetracyclines, therefore, should not be used in this age group unless other drugs are not likely to be effective or are contraindicated. In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, use lower doses, and, in prolonged therapy, determine serum levels. Photosensitivity manifested by an exaggerated sunburn reaction has been observed in some individuals taking tetracyclines. Advise patients apt to be exposed to direct sunlight or ultraviolet light that such reaction can occur, and discontinue treatment at first evidence of skin erythema. Studies to date indicate that photosensitivity does not occur with MINOCIN Minocycline HCl. In patients with significantly impaired renal function, the antianabolic action of tetracycline may cause an increase in BUN, leading to azotemia, hyperphosphatemia, and acidosis. Pregnancy: In animal studies, tetracyclines cross the placenta, are found in fetal tissues, and can have toxic effects on the developing fetus (often related to retardation of skeletal development). Embryotoxicity has been noted in animals treated early in pregnancy. Safety of use during human pregnancy has not been established. **Newborns, infants and children:** All tetracyclines form a stable calcium complex in any bone-forming tissue. Prematures, given oral doses of 25 mg./kg. every 6 hours, demonstrated a decrease in fibula growth rate, reversible when drug was discontinued. Tetracyclines are present in the milk of lactating women who are taking a drug of this class. Safe

use has not been established in children under 13.

Precautions: Use may result in overgrowth of nonsusceptible organisms, including fungi. If superinfection occurs, institute appropriate therapy. In venereal diseases when coexistent syphilis is suspected, darkfield examination should be done before treatment is started and blood serology repeated monthly for at least four months. Patients on anticoagulant therapy may require downward adjustment of such dosage. Test for organ system dysfunction (e.g., renal, hepatic and hemopoietic) in long-term use. Treat all Group A beta hemolytic streptococcal infections for at least 10 days. Avoid giving tetracycline in conjunction with penicillin.

Adverse Reactions: (Common to all tetracyclines, including MINOCIN) GI: (with both oral and parenteral use): anorexia, nausea, light-headedness, vomiting, diarrhea, glossitis, dysphagia, enterocolitis, inflammatory lesions (with monilial overgrowth) in anogenital region. **Skin:** maculopapular and erythematous rashes. Exfoliative dermatitis (uncommon). Photosensitivity is discussed above ("Warnings"). **Renal toxicity:** rise in BUN, dose-related (see "Warnings"). **Hypersensitivity reactions:** urticaria, angioneurotic edema, anaphylaxis, anaphylactoid purpura, pericarditis, exacerbation of systemic lupus erythematosus. When given in high doses, tetracyclines may produce brown-black microscopic discoloration of thyroid glands; no abnormalities of thyroid function studies are known to occur. In young infants, bulging fontanels have been reported following full therapeutic dosage, disappearing rapidly when drug was discontinued. **Blood:** hemolytic anemia, thrombocytopenia, neutropenia, eosinophilia.

NOTE: Concomitant therapy: Antacids containing aluminum, calcium, or magnesium impair absorption; do not give to patients taking oral minocycline. Studies to date indicate that MINOCIN is not notably influenced by foods and dairy products.

*Indicated in infections due to susceptible organisms. Culture and sensitivity testing recommended. Tetracyclines are not the drugs of choice in the treatment of any staphylococcal infection.

Liticogenic Disease

TO LISTEN TO COURT testimony regarding an accident, the average indiscriminating person might well conclude that nearly any disease or disability can potentially result from an accident. Plaintiffs' attorneys have astutely garnered from their clients' experiences an exhaustive list of ailments and complaints from A to Zed—as possible, if not probable, sequels of an accident.

"After all, there is nothing to lose!" Why not incriminate an accident for that headache, that crick in the neck, that twinge in the back, that you-name-it, that mysteriously appears sometime *after* an accident in the victim who was "never subject to previous headaches, cricks, or twinges!"

Unfortunately, qualified and expert testimony has established that a remote three-to-four-year-old non-organic strain, without bruise, fracture, laceration or muscle rupture, has caused obvious disease or contributed to pre-existing disease.

The *post hoc ergo propter hoc* fallacy dies a hard death; it has persistently plagued logicians down the centuries and is still accepted by the untutored and exploited by the unscrupulous. Consecutiveness *per se* does not imply causality and should never constitute a basis for sound medical doctrine.

Neither incidents nor accidents cause disease. If an injury has been sustained, the victim will suffer the effects of that injury immediately. Any accident which does not cause immediate physical distress is indeed minor and represents nothing more serious than a non-organic strain, or contusion, comparable to what any athlete might experience after strenuous activity. Such discom-

fort is physiologic, not organic. Even if the injury is severe enough to cause organic damage (a fracture, muscle rupture, ligament tear, skin laceration), these injuries heal in a more or less scheduled period of time. When healing is complete most of the sequelae of that injury are terminated. The chapter on that incident is closed.

Calling to mind other ailments, symptoms, aches and pains, which may continue for months or even years after the usual healing period for the specific injury has passed, occasionally becomes the occupation of a plaintiff's attorney who endeavors to relate it to the litigious incident. To indulge in this type of machination merely delays the search for a medical cause of ailments, which may be obvious from physical findings, laboratory, or x-ray studies. The patient and his attorney, instead, proclaim the incident as the etiologic factor and with that another case of "liticogenic disease" has been born.

Litigation disease has its own syndrome: the etiology relates to an incident of libelous injury; subjective complaints are referrable to almost any extant set of symptoms; physical, laboratory and x-ray findings are irrelevant and immaterial, though very often they do disclose the correct diagnosis, which is then given the "post hoc, ergo propter hoc" causality; therapy consists of an almost endless series of non-beneficial treatments and the prognosis is contingent upon the outcome of the pending lawsuit.

"Liticogenic disease" is not catalogued in medical annals. But it does exist.

Editor Emeritus

Dr. Lafayette Houghton Bunnell of Winona County

THE PAPER by Dr. Harnagel* of this issue of MINNESOTA MEDICINE, calls attention to an historically interesting Minnesotan, Dr. Lafayette Houghton Bunnell, whose association with the discovery of the Yosemite Valley of California is interestingly presented. Bunnell's medical activities included military service in 1846 and 1851 and he evidently served again during the Civil War after receiving a medical degree (honorary) from the LaCrosse Medical College. The author states that Bunnell settled in Homer, a few miles south of Winona, "after the Civil War" and "that he practiced medicine" (sic). Dr. Lafayette Bunnell and his father, Dr. Bradley Bunnell, are mentioned in "History of Medicine in Winona County" published in MINNESOTA MEDICINE in 1940.¹ Comments there confirm Bunnell's visit to the LaCrosse area prior to the War, but also notes

that his residence in the Homer area was first recorded in 1871, and that "there is no indication of his having practiced his profession while in Winona County." Dr. Bradley Bunnell practiced in Homer from the early 1850's to his death in 1857, a period when deaths in the area resulted from such diseases as malaria, cholera, typhoid fever and scarlet fever. The socio-economic status of medical practice is illustrated by the 1855 activities of another Homer physician, who was listed as a physician and surgeon, justice of the peace, surveyor and coroner. The story of Lafayette Bunnell's varied activities and especially his explorations well deserve the attention of Minnesota physicians and we should be thankful that Dr. Harnagel submitted his paper to MINNESOTA MEDICINE.

1. This History was presented in several parts, in separate numbers of Minnesota Medicine, beginning in April, 1940 (p. 252). The information about the Drs. Bunnell is found on page 247 in the June, 1940, issue. The name of the author is not indicated.

Bilateral Hip Arthroplasty after Renal Transplantation

THE ARTICLE BY Woods,* et al., in the December issue of this Journal, outlines a successful result in the total rehabilitation of a patient with end stage renal disease and bilateral aseptic necrosis of the hip. Major advances in the areas of transplantation immunology as well as surgical techniques have lifted organ transplantation beyond an experimental exercise to a clinically practical and useful procedure. The best results continue to be in those patients who have received an organ from a living related donor. The rehabilitation in this group is shorter, post-transplant renal function is usually immediate, and fewer rejection episodes occur. Small doses of immunosuppressive drugs are therefore required. On the other hand, the number of patients receiving kidneys from cadaver donors is steadily increasing. In this group of patients the complications from

recurrent rejection and immunosuppressive therapy are significantly greater. These problems have been recently outlined by Najarian and Simmons,¹ and include infection, an increased incidence of malignancy, Cushing's disease, gastrointestinal hemorrhage, cataracts, thromboembolic disease, hypertension, and alteration in calcium metabolism. One of the most disturbing barriers to the successful rehabilitation of transplant patients is avascular necrosis of the femoral heads, femoral condyles, and to a lesser degree other bones. The etiology is unknown, but appears definitely related to high doses of steroids. As the dosage of steroids necessary to sustain immunosuppression have been decreased, most transplant centers around the country have noticed a similar decrease in the incidence of avascular necrosis. The problem, however, remains, and the treatment for the most part has been symp-

*See page 1103, December, 1972 issue.

tomatic. Treatment by prolonged periods of non-weight bearing with crutch support would appear at best questionable, for it is doubtful that the bony lesions can revascularize sufficiently to restore normal architecture in the presence of maintenance steroids.

If the patients' symptoms are unrelieved by conservative management and the joint architecture has been severely altered, total joint replacement arthroplasty may be indicated. However, this recommendation must be tempered by the understanding that the risk of surgery in this group of patients is clearly greater than the general population and the complication of wound infection

alone could well lead to deterioration of renal function and allograft rejection.

The authors are to be complimented on the excellent results they obtained in this particular case. Certainly we would agree completely that patient motivation is an important factor in the rehabilitation of these patients. Hopefully in the future, the immunological barriers to successful organ transplantation can be overcome and immunosuppressive drugs therefore deleted altogether. In the meantime, we can safely say that problems relating to musculo-skeletal disease following renal transplantation will continue to be with us.

Concurrence of Achalasia with Adenocarcinoma of the Stomach

SHAFFER AND JACOBSON* particularly emphasize early detection of malignancy in patients with achalasia by regular, periodic examinations. Yet there exist several good reasons why recognition of malignancy may go unnoted for some time.

Their case report again reveals how difficult it is to detect early malignancy in a patient with previous diagnosis of achalasia. Inasmuch as the incidence may be even greater than three percent, as stated by the authors and others, this does raise serious question as to how often patients

with achalasia should be thoroughly studied, and also to what extent. Obviously, treatment by the Heller procedure is indicated early as a prophylactic measure as well as for the relief of symptoms. Unfortunately, x-ray studies can only be relied upon with limited success, and endoscopy with biopsy, which may be more accurate, is technically more uncomfortable and difficult. I am not even convinced that the results of cytological studies by the brush technique are worth their routine use.

Actinomycosis of the Female Genital Organs

RICHTER ET AL.* have presented an excellent review of one of the rarer clinical manifestations of actinomycosis. Actinomycosis, now considered by some authorities to be a bacterial infection, is felt to be decreasing in incidence. There is no way to substantiate this clinical impression. There are no reliable skin tests nor is the disease reportable. This decrease may be due to the introduction of antibiotics, especially penicillin. However, earlier diagnosis as well as more effective therapy may also have reduced reportable cases. Actinomyces israelii, which is responsible for most human infection, is an anaerobe which has never been demonstrated in soil, plants or other fomites

outside the body. Therefore, the theory of endogenous implantation is generally held to be most likely. From its original site, spread may occur by direct extension along sinus tracts and by metastases.

Penicillin is the drug of choice in this condition. Prior to its introduction, the prognosis in actinomycosis was grave. Antibiotics have changed this dramatically. Whenever possible the combined approach of both surgery and antibiotics is desirable. It should be further emphasized that antibiotic therapy must be administered in adequate dosage ranges and for a sufficient period of time.

In-Hospital Postpartum Approach to Family Planning

DESPITE THE RECENT well-publicized decrease in birth rates in Minnesota and the United States, there is evidence that many of these births are "unwanted." In some areas where abortion on request is available, as in New York, nearly 300 pregnancy terminations are carried out for the resident population for every 1,000 live births. Because of our current restrictive abortion law, comparable figures are not available for Minnesota. However, the National Center for Disease Control estimates that 1,500 to 2,000 Minnesota residents now seek abortion elsewhere each year, and approximately 5,000 illegitimate births occur annually in the state. These data suggest that a substantial number of unwanted pregnancies occur. While there is evidence that many patients who have a negative reaction to their pregnancy during its early stages develop a positive acceptance of it later, the evidence, nevertheless, clearly suggests that there is a continuing need for effective birth control programs in our state.

An effective program requires that potential acceptors of a birth control method be reached, taught, prescribed for, and followed. Postpartum and Gyn wards contain a concentration of known fertile women who are available for group teaching, and who are at this time generally highly motivated towards accepting a birth control method. In-hospital family planning programs which concentrate on postpartum and postabortal patients are for these reasons effective and efficient.

A program of this type has been operative at Hennepin County General Hospital for five years. All patients are invited to attend a group discussion of family planning methods, which is led by a nurse who has been specially trained for this purpose. All methods are described together with a discussion of some basic physiology, and a short movie is shown. Patients are invited to ask questions, and following this, they are visited at the bedside where further discussion can be carried out in private with the nurse. At this time, the patient indicates whether she is interested in birth control or not, and if so, what her choice of method is. The nurse conveys this information to the physician who prescribes for the patient whatever he considers appropriate. Patients are free to make their own choice with the physician,

and there is no pressure or coercion of any sort applied. More than 90% of the postpartum patients accept some method of contraception.

The results of early puerperal insertion of the intrauterine device are presented in a paper in this issue.* Although the "fall-out" rate has been high, the convenience, simplicity, and safety of this method make it an appealing one. Recent improvements in the design and performance of IUDs give promise of increasing the popularity of this technique. Over the past two-year period, 52% of the patients have been choosing the oral contraceptive. This ordinarily is started on the day of discharge, but the use of pills is modified for those who nurse. Our five-year experience with approximately 3,500 patients following this routine has documented to us the safety, effectiveness, and lack of significant side effects or problems with this approach. Currently, 11% of the patients are accepting permanent sterilization carried out by postpartum tubal ligation. The use of the rhythm method, foam, condoms, and diaphragms accounts for 6%, and the remaining patients have no need for or do not choose to use any form of contraceptive.

The patient follow-up portion of the program has shown that a very large increase in patient attendance at postpartum clinics has occurred. Patient acceptance and retention of information and advice is high when it is presented in a group teaching setting by an interested and highly qualified nurse. The sessions are unhurried, informal, and relaxed. The atmosphere is conducive to free discussion. The almost universally favorable patient reaction is probably aided by the fact that the discussion leader is female. The overworked physician, on the other hand, is likely to be preoccupied with other problems of seemingly greater momentum. In many cases, he does not initiate a discussion of birth control methods with his patient at all, and should the patient bring it up, it is likely to receive cursory attention.

The approach described saves time for the busy physician without in any way interfering with his prerogatives with regard to patient management. Family planning programs should be made a routine part of postpartum care in all hospitals.

Donald W. Freeman, M.D.
Minneapolis, Minnesota

Letter to the Editor

The Technological Challenge

AS ONE STUDIES the events of the history of mankind, it becomes apparent that ordinary political events have occurred in an ever-changing, kaleidoscopic fashion: even in what we look back upon as relatively stable times, such as the Victorian Era. In contrast, cultural changes have occurred in great cycles, lasting, in many instances, for centuries. As an example of each, the entire history of the French Revolution and its aftermath: from 1789 to the fall of Napoleon, comprised a time span of about 25 years, whereas the Renaissance, even in Italy, lasted for the better part of three centuries. Somewhere around the beginning of the eighteenth century, a pronounced speedup in technological development began; the beginnings, we have learned to call the Industrial Revolution. That technical and scientific advances have continued at an ever faster pace since then is readily evident. What we may not as yet be prepared to accept is the possibility that this cultural revolution may, like others, at some time decelerate.

Technical advances are, for many reasons, not consistently favorable to the welfare of humans exposed to them. The enslavement of people in the factory system early in the industrial revolution is a familiar story. Today, social unrest, pollution, and particularly, the establishment of mammoth industrial and political systems which stifle individuality and respond inadequately to human needs appear as indicators of what may be limits to the desirability of technical advance. In spite of computers and split atoms, it should not be hard to see that, today as always, man enters the world naked and defenseless, proceeds to maturity with a deluded sense of his personal significance, and then passes relentlessly into oblivion. During this journey from nothingness to nothingness, his basic drives, his fears, and his inner needs seem not significantly different from what they must have been at the dawn of history.

The role of the physician in society is traditionally closely related to man's emotional needs, and the role of the "Medicine man" in recent primitive societies parallels those found by archeologists in ancient civilizations. It should be obvious that he has been looked to for something more than the application of technical knowledge, and it is for this reason that the relationship between the modern technological revolution and the medical pro-

fession holds even greater significance than is the case in other lines of human endeavor. In a short span of time, the rapid accumulation of scientific medical information has had a drastic effect upon relationships between the physician and the public.

There can be no question but that the medical discoveries of the past century comprise one of the greatest blessings ever bestowed upon the human animal. However, certain ancillary effects have had their ambivalent aspects. One noteworthy result is that, whereas formerly, the doctor measured his success by what the lay community thought of him, today he increasingly regards himself in terms of his image in the eyes of his colleagues. That such a development is predominantly fortuitous is undeniable; whereas the public could, and has, gullibly worshipped physicians whose performance was less than competent, peer acceptance is, to a far greater degree, based on reality. On the debit side, however, is the fact that the profession has assumed a near exclusive emphasis on technical skill and knowledge, and has difficulty in judging the humanitarian aspects of medical practice.

In recent years, in this country and elsewhere, the great bureaucratic institutions of today: political and private, have entered into the medical picture. Themselves the product of the technological age, and thereby blinded by the excesses of its changes, these institutions have proposed changes in the medical world which stress increased organization of both doctor and patient. Where results are in evidence, they exhibit a lack of concern for human values: in some cases, for both those of the provider and of the recipient of medical care.

Strangely, the United States, which leads the world in so many aspects of technology, has lagged behind other countries in technically organizing its medical care. It seems possible that the country's traditional linkage with a not-so-remote frontier society, with its intimate personal relationships, may have something to do with this. In Great Britain, a paradoxical system has been developed, under which, a sizeable segment of the profession has been virtually stripped of all its tools. The remaining part, removed from the personal lives of the patients, has exclusive use of the machines, which are glorified via a rigid mechanism of lengthy initiation and qualification

to its privileged ranks. The hierarchy inflicts many casualties upon those seeking to qualify for the use of the technical, and the victims are, in essence, left with no place to turn. The result is a mass exodus of professionals to 'lagging' nations, such as the United States, where the medical scene still offers them an opportunity to be useful.

In Russia, personal physician relationships have been relegated to poorly trained and compensated, individuals, who, while called physicians, are, in essence, paramedical personnel. This medical scapegoat must be at the beck and call of all. However, the limited skill that is deliverable can hardly lead to prompt access to good medical care.

In the United States, the medical profession has not, as yet, become engulfed into the massive, technically-oriented bureaucracy. Nevertheless, technical progress has had its effects. The ranks of primary physicians have been steadily shrinking in proportion to the population. Medical educational institutions have failed to keep up with demand, partly because the cost of technical teaching has increased, and partly because preoccupation with the technical has resulted in a dearth of attention to socio-economic matters. Medical costs have skyrocketed because the machines have been so expensive. In spite of this, it seems noteworthy that the world's most technically-advanced nation has afforded itself the time to adjust to the times in a more far-sighted, complete manner than its neighboring countries. In spite of drastic differences of opinion, virtually no segment of American society proposes a European solution to the problems of medicine.

Today, then, American doctors find themselves

challenged by what may be the greatest opportunity ever afforded a profession anywhere. It comprises placing technology where it belongs in the medical scene: in a position which places humanity and its needs first, with the machine secondary to it. While everyone agrees in principle with such a philosophy, the actual state of affairs is that many professionals are so obsessed with technical know-how and the pursuit of scientific facts that they regard these achievements as ends in themselves.

The time is overdue for the American medical profession to place studies of the needs and requirements of human beings in their proper perspective. Eminence in the profession must no longer be arrived at because of mastery of the technical alone, and recognition of accomplishments in the spheres of the application of medicine to people must be recognized achievements of at least the proportions of scientific discovery. Basic understanding of the needs of humanity must no longer be held as something too unsophisticated to merit the attention of those who would consider themselves professional leaders. The truly educated possessor of an M.D. degree must be possessed of an intelligent view of the forest, humanity, in addition to the trees of scientific fact, and until he does, he can hardly be expected to do other than distort the picture. If, however, he achieves this type of insight, he can be a significant factor in extending the life of our 300-year old cultural revolution: dealing with its excesses as a significant aspect of the pathology of our troubled civilization.

Henry B. Blumberg, M.D.
St. Paul, Minnesota

OLD DOC HESS SAYS: If you do not want your autographed picture to be relegated to the hidden file, frame it, attach the hanging hook, the nail to hang it on and the hammer to pound the nail; then to be certain, hang it yourself! . . . C.O.R.

No argument is needed to show what transforming power the mind can exert. The energy set free by the magic agencies of hope, courage, desperation, fanaticism, or by the enthusiasm for a great cause, may reveal the possession of a force undreamed of, or so husband the resources of the body as to keep the flame of life burning for a time when the oil seems exhausted.—James J. Putnam [1846-1918]

Obstetrics and Gynecology

Insertion of Intrauterine Devices

In the Early Postpartum Period

ROBERT A. DIAMOND, M.D. AND DONALD W. FREEMAN, M.D.

IN 1967, AN EVALUATION was made of the family planning done at Hennepin County General Hospital, and a program established to follow patients using oral contraceptives or intrauterine devices. This evaluation indicated that the percentage of patients who returned for postpartum examination was very low, suggesting that those who needed contraception most—those who received medical attention only for labor, delivery, and postpartum hospitalization, were not being served. To improve this situation it was decided to explore the idea of inserting intrauterine devices prior to discharge from the hospital.

A review of the literature showed early puerperal insertion to be safe but it was associated with a definite increase in the expulsion rate. In early 1966, the Population Council had organized and supported a large scale worldwide postpartum program in family planning. One of their early reports, along with one by London and Anderson^{2,6} from Los Angeles County General Hospital, showed considerably lower expulsion rates. Their reports gave us the enthusiasm to begin inserting intrauterine devices in the puerperium with the hope that the high percentage of our patients who never returned would then be provided some contraception.

Procedure

After delivery, all patients on the postpartum ward are visited by a family planning nurse who explains to them the different forms of contraception. Ninety percent of our delivered patients are discharged on some form of contraception. Over 50% of them choose oral contraceptives which are started on the day of discharge unless the patient is nursing. An intrauterine device is accepted by 20 to 25%, and the remainder are sterilized by tubal ligation or use other contraceptive methods.

If an intrauterine device is chosen, it is inserted on the day of discharge. The majority are discharged on either the fourth or fifth postpartum day. Routine postpartum discharge pelvic examination is done in the dorsal lithotomy position. A clean speculum is carefully inserted into the vagina and the cervix exposed. The speculum is then removed, and a bimanual examination done to assess the size, position, and consistency of the uterus. The speculum is reinserted and the anterior lip of the cervix grasped with a ring forceps. The device is then inserted as high into the uterine cavity as possible using the regular type inserter. The patient is re-examined after the speculum is removed to be sure that no part of the device is in the cervical canal. Patients are instructed to return for a checkup at six weeks' and three months' postpartum and at yearly intervals.

Results

The results are summarized in Table 1.

Between September 1, 1968 and December 31, 1970, a Lippes Loop D was inserted into 643 women on the day of discharge from the postpartum ward. Of this group 142 patients (22%) failed their postpartum appointments. Between

From the Department of Obstetrics and Gynecology, Hennepin County General Hospital and the University of Minnesota Medical School, Minneapolis, Minnesota.

Presented at a Meeting of The Minnesota Society of Obstetrics and Gynecology, April 29, 1972, Rochester, Minnesota.

May 1, 1971 and February 15, 1972, a Standard Size Dalkon Shield was inserted into 219 women on the day of discharge. There were 40 patients of this group (19%) who failed their postpartum appointments.

In the first six weeks after insertion, there were 303 expulsions of Lippes Loop D (60.5%) among those who returned for follow-up. There is no information about the 142 patients who failed their postpartum appointments, but even if all had retained the device, the expulsion rate would be 47% at six weeks. An additional 43 loops were expelled within one year of insertion for a total of 68% of those followed. Of those followed in the Dalkon series, there were 86 expulsions (48%) within the first six weeks. The follow-up for that group was too short for an evaluation at one year.

In the Lippes Loop series, there were no serious infections, but two devices were removed in association with a mild pelvic inflammatory disease. Seventeen patients had the device removed because of menorrhagia and seven due to dysmenorrhea. There were six pregnancies, all with the device in place. There were no known perforations. In the Dalkon group, five patients had the device removed for menorrhagia. There were no serious infections and no perforations. There was one pregnancy with the device in place.

Discussion

Early postpartum intrauterine device insertions are easy to perform and are painless. The availabilities and motivation of the patient at this time are other advantages. Furthermore, perforation is extremely rare and there appears to be no increased risk of infection or bleeding. The involution of the uterus is not affected.

The high expulsion rate, however, is a real problem. The results of several studies are summarized in Table 2.¹⁻⁶ Higher retention rates are reported when a special long inserter and devices with special long tails are used.^{1,6} However, the best results have been obtained with a new device called the Petal IUD. Rashbaum⁴ has reported 522 early postpartum insertions with this device, with 460 of these done on the delivery table. The expulsion rate was only 5.5%. Eight percent,

TABLE 2
Comparative Results of Early Puerperal
Intrauterine Device Insertions

Cooperative Statistical Program	Insertions		Expulsions	
	—		45.2%	
Phatak (India) 1965-1966 Lippes Loop D	903		37.8%	(at 3 months)
Population Council (Singapore) 1966-1968 Lippes Loop D with special long inserter	3168		18 %	(at 3 months)
London and Anderson (Los Angeles) 1966 Lippes Loop D (615 of 899)	899		20 %	
Population Council (Thailand) 1965-1969 Lippes Loop D with special long inserter	7172		19 %	(at one year)
Rashbaum (Beth Israel, New York) 1971 Petal IUD	522		5.5%	
Hennepin County General Hospital 1968-1972 Lippes Loop D	643		60.5%	(at 6 weeks)
Dalkon Shield	219		48 %	(at 6 weeks)

however, were removed for medical problems and about 7% for other reasons. There were also 11 pregnancies (2.1%) but no perforations.

Most spontaneous expulsions and indicated removals for pain and/or bleeding occur within the first three months. Reinsertion of a device three months postpartum can be carried out when necessary and little has been lost. Meanwhile, the remaining patients who have had early postpartum intrauterine device insertions have been afforded pregnancy protection, and for them, further measures may not be required. This is of particular value where patient follow-up is poor.

Summary

Despite the advantages of convenience, safety, and economy afforded by early puerperal insertion of intrauterine devices, the current high expulsion rate probably precludes acceptance of routine use of this technique. However, the reported better retention of a new device and the use of different inserters with the older device suggests that further studies may be worthwhile.

Fracture Conference

Traumatic Spondylolisthesis

EDWARD D. HENDERSON, M.D., RAY E. SANTOS, M.D., RICHARD T. CHIROFF, M.D.
AND EINER W. JOHNSON, JR., M.D.

Dr. Richard T. Chiroff:

The patient was a 20-year-old white man who was involved in an automobile accident. He had been thrown from the vehicle in which he was riding and had been unconscious for a short but indefinite period. His initial emergency resuscitative care had consisted of intravenous fluids, whole blood, and immobilization of an injured left arm. He was referred here after his condition had stabilized. On examination the patient was conscious, and there were multiple abrasions and contusions over his face and scalp. The left arm was already in a plaster cast with the elbow at 90 degrees; the neurovascular status of the left hand was normal. The patient complained of some pain in his left arm and also in the left upper quadrant of his abdomen and low in his back. On neurologic examination the extremities were normal. Also his vital signs were normal and stable.

Dr. Edward D. Henderson:

From the Mayo Clinic and Mayo Foundation, Rochester, Minnesota. Fracture Conference, June 24, 1968.

Dr. Milicic, what do you see on the roentgenograms? (Figure 1).

Dr. Milicic:

There is moderate forward displacement of the fourth lumbar vertebra. This vertebra is probably fractured laterally.

Dr. Henderson:

This is called "traumatic spondylolisthesis" and is not too common. Drs. Bickel and Sullivan wrote a paper on it a few years ago.

Dr. Chiroff:

In addition to this fracture, there was a transverse fracture of the shaft of the left humerus, which was treated by open reduction and fixation with a compression plate. However, here we are concerned with the spondylolisthesis. The patient was admitted to the intensive-care unit and was watched closely because of possible internal injuries along with the fractures. His course was uneventful during the next few days, his vital signs remained stable, and no condition of serious consequence developed in his abdomen. The left upper quadrant pain subsided. It was decided to

Fig. 1 (Case 1)—At admission. *Left*, Anteroposterior view, showing fractures of all lumbar transverse processes on left and of L-5 on right. Overlapping projection of inferior margin of L-5 with superior margin of sacrum suggests anterior displacement of L-5. *Right*, Lateral view shows a grade 3 "traumatic spondylolisthesis" of L-5 on sacrum with fracture of posterior elements of L-5.

treat the traumatic spondylolisthesis with skeletal traction, and two Steinmann pins were inserted in the distal part of the femurs for this purpose. Figure 2 shows the method by which traction was applied. Incidentally, the patient was six feet eight inches tall and extended over the end of the bed.

Fig. 2 (Case 1)—Balanced traction apparatus with pin in each distal femur. Traction is adjusted so that buttocks are suspended just off bed.

Dr. Henderson:

You may think we put him in traction in this position because he was so tall, but that is not the case. Enough weight was added to just get his buttocks off the bed. This, as you will see, is successful in reducing a traumatic spondylolisthesis. I did this about 10 years ago on another patient and I knew it would work.

As shown in Figure 3, the reduction was successful, leaving spondylolisthesis of less than grade 1 as compared to grade 3 before treatment.

Fig. 3 (Case 1)—Roentgenograms made with portable apparatus during balanced traction. *Left*, After one week of traction, anterior slip of L-5 on sacrum is now approximately that of grade 1 spondylolisthesis. *Right*, After one month of traction, slip of L-5 on sacrum is now minimal. Fusion was carried out three days later.

Dr. Chiroff:

At approximately six weeks after the application of the traction apparatus (seven weeks after the original injury) the apparatus was removed and a spinal fusion was performed (Figure 4). At the time these roentgenograms were made, the patient was wearing a corset-type back support and was ambulatory on crutches.

Dr. Henderson:

It is very difficult to read these roentgenograms, but I think the anterior edge of the sacrum can

Fig. 4 (Case 1)—At three and a half weeks after fusion of L-4 to sacrum. *Right*, Anteroposterior view shows some evidence of forward displacement of L-5 on sacrum. Fractured transverse processes are healing. *Left*, Some loss of correction is evident.

be seen almost completely underneath the body of the fifth lumbar vertebra. The condition now is between grade 1 and grade 2 spondylolisthesis. You can see the defect in the pars interarticularis posteriorly.

Dr. Chiroff:

The second case is another example of traumatic spondylolisthesis in a 15-year-old white boy who was referred to the Mayo Clinic because of progressive scoliosis and sciatic pain down the left leg. The patient had no history of back difficulty or problem with his leg until March 1960 when he noted pain rather suddenly one day after broad jumping. He stated that at that time he had been broad jumping for more than a week and had the pain only after one particular jump. There was no radiation of the pain or paresthesia

in the leg, nor were there any problems with his bowel or bladder. He denied having any specific back pain at that time. He was not severely disabled at the time of onset of pain but said the pain had been getting progressively worse from March until July, and his mother stated that he had grown approximately three inches in the previous six months and that she had noted the scoliosis to be progressing.

On examination here, in August 1960, there was an obvious thoracolumbar scoliosis and tenderness in the posterior aspect of the left thigh. The patient leaned to the right when he stood. Straight leg testing gave positive results on the left side at 60 degrees, and the back motions were markedly limited. The roentgenograms are shown in Figure 5.

Fig. 5 (Case 2)—At admission, five months after injury, anteroposterior, lateral, and three-quarter views of lumbar spine all show spondylolisthesis of L-5 on sacrum with bilateral defects of neural arch.

Fig. 6 (Case 2)—Shortly after bone grafting from L-4 to sacrum. No attempt at reduction was made prior to insertion of grafts.

Fig. 7 (Case 2)—Anteroposterior (*Left*) and lateral (*Right*) views of lumbar spine two and a half years postoperatively. Flexion-extension views at this time showed no motion at L4-5 or L5-sacrum.

Dr. Henderson:

These show grade 3 spondylolisthesis of the fifth lumbar vertebra forward on the sacrum.

Dr. William H. Bickel:

One thing that strikes me is that the anterior superior lip of the sacrum is rounded off. It makes you wonder whether there was a pre-existing lesion there.

Dr. Henderson:

I agree. This may not be an acute spondylolisthesis. However, there surely is strong presumptive evidence of the traumatic origin of the symptoms at least and probably also of the roentgenographic findings. I thought that this condition justified surgical treatment. A spinal fusion from L-4 to the sacrum was done but no attempt was made to reduce the forward positioning of L-5 (Figure 6). Two and one-half years later he had

a solid spinal fusion and no complaints (Figure 7).

The two patients with acute spondylolisthesis are interesting and challenging. The first should have been put back in traction after the operation, but he had become so depressed in traction that this was impossible. Had we done this, however, we would probably have maintained the reduction. Also, it is interesting to speculate on whether or not we could have gotten union of the pars interarticularis fracture just by keeping him in traction and possibly have avoided the operation entirely. But his mental state prevented us from even thinking of this. In the second case, although five months had elapsed between the injury and referral of the patient to us, it is also interesting to speculate whether or not traction would have reduced the forward position of L-5. Again, practical considerations—this time, expense—prevented us from pursuing this approach.

Flint Laboratories

"Thyroid Disease as a Late Sequela of Radioactive Fallout" is the title of a new film from the Flint Laboratories division of Baxter Laboratories, Inc.

The 30 minute, full color-sound film was produced by Flint in conjunction with Brookhaven National Laboratory and the Atomic Energy Commission. It specifically covers the subject of thyroid disorders as related to accidental fallout of radioactive iodine on the people of Rongelap Island in 1954.

The film has won the Gold Camera, Cine, and New York Film Festival awards.

Booking arrangements may be made through: Professional Services Department, Flint Laboratories, 200 Wilmot Road, Deerfield, Illinois 60015.

Cover Photo

"Winter Scene"

This month's cover is a painting by Dr. Frances E. Schaar, a pediatrician in private practice in Minneapolis. She claims to be only a "Sunday painter" doing painting only for her enjoyment. The winter scene features children in one of Minneapolis' parks and was done by her three or four years ago after seeing a newsphoto printed in the Sunday Supplement.

Dr. Schaar was born in Wisconsin and taught school there. In 1947 she came to Minnesota and joined the staff of the Student Health Services at the University of Minnesota where she taught anatomy to nurses and medical technologists. Later she went into pediatrics as a resident.

Hypersexual Behavior Complicating Levodopa (L-Dopa) Therapy

SIDNEY K. SHAPIRO, M.D.

WITH THE INCREASED use of Levodopa in the treatment of Parkinsonism, complications from its administration are becoming more apparent. There are three large groups of complications: (1) Gastrointestinal effects; (2) Abnormal motor activity; and (3) Psychiatric disturbances. Other complications encountered less frequently are hypotension and associated traumatic fractures resulting from falling.

Frequent Psychiatric Complications

According to other reports, psychiatric complications may vary from 10 to 30 percent with 30 percent probably being more accurate. Among the side effects encountered psychiatrically, hypersexual behavior is one of the least common, being present in less than one percent of patients. This complication has received mention in the lay press, and perhaps, facetiously, some have suggested this drug may be the answer to impotence or to a decreasing sexual drive.

This report describes an interesting Parkinsonian patient who had a marked change in behavior in his sexual drive during Levodopa therapy. In addition, it calls attention to other psychiatric disturbances that may occur.

Case Report

A 76-year-old patient presented a classical picture of Parkinsonism which had been present for forty years. He had influenza in 1918 and subsequently developed postencephalitic Parkinsonism. On examination there was masking of the face, slurring of speech, moderate rhythmic tremor of the right hand and right upper extremity and a mild rhythmic tremor of the right foot. Moderate rigidity was present in the right arm and right leg and mild rigidity in the corresponding structures on the left. On examination of the mental status, the patient was oriented in the three spheres. No psychotic manifestations were in evidence and his stream of conversation was normal. The decision to give him a course of Levodopa therapy was made as a result of a progression in his symptoms over a two year period. Levodopa therapy was commenced on June 7, 1971.

The patient was initiated on gradually increasing doses of Levodopa over a period of 27 days and finally reached the level of five grams per day, one gram being given at 8 a.m., ½ gram at 10 a.m., ½ gram at 12 noon, one gram at 2 p.m., ½ gram at 4 p.m., and ½ gram at 6 p.m. and one gram at 8 p.m. The patient responded well, noting improvement in his gait and agility. Rigidity in his right leg decreased from moderate to mild. Associated movements reappeared in the left upper extremity while walking although the right upper extremity still did not swing freely. He also continued to have a mild tremor of the rhythmic type involving the right hand. His facial expression became more animated. Slurring of speech decreased and his general physical status seemed to show a definite improvement.

However, as the dose of Levodopa increased, the patient developed a marked increase in his libido. Advances towards the nurses on one station necessitated his being moved to another station. In spite of this change, this troublesome side effect persisted. A trial of Mellaril failed to decrease his renewed interest in sex. The patient became restless and developed difficulty sleeping. Finally, the patient was discharged on Levodopa, five grams daily at which time his social relationship with the nursing staff and other patients had deteriorated significantly. For example, he made little effort to avoid exposing himself, and made amorous advances towards some of the younger female patients on the floor.

Following the patient's discharge from the hospital, he was seen in the office on July 16, 1971. His increased sexual interests had caused him to become extremely nervous, restless, and unable to sleep. Interestingly, he then had stopped all of his Levodopa voluntarily stating that he would rather have his former disability than the increased sexual stimulation.

Readmission to the hospital was necessary because of a deterioration in his Parkinsonism and his medicine was re-regulated on a dosage of Artane five mg. three times a day, Benadryl 50 mg. three times a day and Levodopa 500 mg. four times a day. Some improvement in his Parkinsonism occurred, although at this dosage of Levodopa he continued to have excessive but tolerable sexual rumination and anxiety. This basic regime was continued until his discharge from the hospital. Subsequently the patient was lost to follow up care.

Discussion

General Psychiatric Side Effects

Psychiatric side effects of Levodopa therapy

Dr. Shapiro is a Clinical Professor of Neurology, University of Minnesota, Minneapolis. Reprint requests address to: Dr. Shapiro, 1218 Medical Arts Building, Minneapolis 55402.

have been thoroughly reviewed by Dr. Goodwin.¹ In order of frequency, the more common side effects encountered are confusion, delirium, depression, overactivity, restlessness, agitation, psychosis, delusions, paranoia, hypomania and impulsivity, increased anxiety, lethargy, insomnia and vivid dreams. Among the less frequently observed complications are those of hypersexual behavior such as this present patient demonstrates.

Hypersexual Symptoms

O'Brien et al.² reported six out of nine males receiving 4 to 6.5 grams of Levodopa per day had had spontaneous penile erections. Three of these men had been impotent for up to ten years. The reactions were sources of puzzlement and embarrassment to the older men and were usually not revealed unless questioned. Generally the erections were not related to sexual objects and were not accompanied by sexual fantasies. Three of the men, however, reported an increase in libido. One formerly impotent man was able to resume satisfactory sexual intercourse.

Use In Impotence

A trial of Levodopa in a small group of men with primary psychogenic impotence resulted in a transitory improvement in sexual performance in one half of them.³ It must be assumed that Levodopa has a questionable primary value in the treatment of a decreasing sexual drive or impotence in an individual.

In some instances such as our current patient, this increased interest has exceeded the bounds of normalcy and has led to excessive sexual drive and inappropriate behavior. In some instances,

the symptoms of hypersexuality occur in association with other symptoms suggestive of hypomania such as poor judgment, grandiosity, hyperactivity, rapid speech and euphoria. The patient under consideration here demonstrated in addition to the hypersexuality, euphoria, restlessness and sleeping difficulty. Although he had been unable to obtain an erection, he had thought repeatedly about it and felt that he would be able to have an erection in the future. He freely admitted to a greatly renewed interest in sex, and his behavior in the hospital ward came very difficult to control because of his advances toward the nursing staff and female patients.

It is possible that a biochemical effect of dopamine on central nervous system pathways may account for a specific "aphrodisiac" effect. Also, it may be concomitant with improvement in motor function. However, it is felt more likely that the change in sexual behavior is part of a general hypomanic syndrome in the type of patient as described above. Generally the psychiatric side effects of Levodopa therapy are reversible with the adjustment of dosage. In this patient, a decreased dosage failed to completely relieve this troublesome complication although unfortunately the Parkinsonism likewise was not as well controlled as at the higher levels of Levodopa.

Summary

1. Psychiatric complications of Levodopa therapy are common.
2. A patient with hypersexuality—an unusual psychiatric complication of Levodopa therapy—is presented.

Case Report

Polycythemia Vera with Acute Budd-Chiari Syndrome

KLAUS RETZLAFF, M.D. AND JAMES J. MONGE', M.D., M.S.

WE RECENTLY had the opportunity to see a patient with polycythemia vera associated with an acute Budd-Chiari syndrome. The outstanding aspects of the case were obstruction of the hepatic veins and the inferior vena cava, abdominal discomfort, ascites, and hepatomegaly with disturbed liver function. Necropsy examination confirmed the diagnosis.

Case Report

A 55-year-old white female stenographer developed right upper abdominal discomfort in January, 1972 and, after three weeks of mild dyspnea, noted increasing abdominal distress "with a heavy feeling." When she made her first visit to her physician on March 22 (1972) he noted ascites, an enlarged liver, and a non-tender pelvic mass the size of a six-month pregnancy. The white blood count was 11,600 cu mm, the hemoglobin 19.0 grams percent, and the hematocrit 59 percent.

Her doctor performed a laparotomy on March 28, 1972. After 4,000 cc. of straw-colored fluid was aspirated, the liver was noted to be enlarged and nodular. Liver biopsy showed "dilated sinusoids with vascular congestion." The pelvic mass proved to be a degenerated benign leiomyoma weighing 1800 grams; a hysterectomy was done. Following surgery the patient drained massive amounts of ascitic fluid through the incision.

On April 14 the wound dehiscd and she was transferred to -St. Luke's Hospital, Duluth. On arrival she was weak, dehydrated and hypotensive and still draining 400 ml. of ascitic fluid per day. Examination disclosed an ill-appearing woman. Her pulse was regular, the heart tones were normal and the lungs were clear to auscultation and percussion. The neck veins were flat, the hepatojugular reflux was absent, and there was no evidence of cardiac insufficiency. The liver was enlarged to four fingers below the subcostal margin but the spleen was not palpable. No other abdominal masses were noted and pelvic examination was not remarkable. There was edema of the vulva and of both thighs.

Laboratory work revealed a white blood cell count of 42,000/cu mm, hemoglobin 19.8 gms. percent, urinalysis normal, blood urea nitrogen 70 mg. percent, serum sodium 126 meq/l, potassium 5.8 meq/l, and chloride 96 meq/l. The serum SGOT was 1,990, LDH 250, and alkaline phosphatase 121. The serum ammonia was 183 mcg. percent. Total serum bilirubin was 1.6 mg. percent, serum albumin 2.1 and serum globulin 1.4 gms. percent.

On April 19, after correction of the dehydration,

hypoalbuminemia and hyponatremia with intravenous fluids, the white blood count was 28,000/cu mm, hemoglobin 15.9 gms. percent, serum albumin 3.8 gms. percent, globulin 1.4 gms percent and blood urea nitrogen 20. A liver photoscintigram showed a very small area of uptake over the right lobe of the liver, a much enlarged left

Fig. 1—Large thrombus originating from left hepatic vein and extending into the inferior vena cava and right atrium.

Fig. 2—Liver Sections: (Left) Fibrotic infarcted right lobe. (Middle and Right) Enlarged and congested left lobe with thrombosed hepatic veins.

From the Duluth Clinic, Duluth, Minnesota.

lobe with irregular uptake, and increased uptake over the spleen and spine.

Extensive bleeding due to portal hypertension was encountered at exploratory laparotomy on April 21. The surgeon noted congested veins in the abdominal wall and in the intestinal mesentery. The left lobe of the liver was large, firm, and markedly congested, whereas the right lobe of the liver was very small and atrophic. Needle biopsy of the left lobe of the liver again revealed dilatation of the sinusoids with destruction of hepatic cells and bile stasis. There was no evidence of hepatitis,

Fig. 3—Left lobe of liver: Congestion and fibrosis with organized thrombus in major hepatic vein (hematoxylin and eosin X 40).

Fig. 4—Left lobe of liver: Marked central congestion and necrosis of parenchymal cells (hematoxylin and eosin X 100).

cirrhosis or malignancy. Ascitic fluid was negative for malignant cells.

Despite having received no transfusions the hemoglobin rose to 16.5 gms. percent on April 25 with an elevated reticulocyte count of 5.3. Serum ammonia determinations, SGOT, and LDH remained elevated. The patient's condition gradually deteriorated and she became icteric. Seven days after operation she began to have upper gastrointestinal bleeding and oliguria, became unresponsive and died two days later.

Necropsy revealed a deeply jaundiced female with right pleural effusion and ascites. The right lung was atelectatic and sectioning revealed areas of old infarction. A small embolus was found in the pulmonary artery to the lower lobe of the left lung. There was an acute inflammatory infiltrate in the pulmonary alveoli with microabscesses and areas of pulmonary infarction. Pseudomonas organisms were cultured from the pleural effusion. The heart was normal size and the coronary arteries showed moderate arteriosclerosis. The large esophageal varices present were intact. There was a large perforated duodenal ulcer and the stomach was filled with bright red blood. The spleen weighed 400 grams and histologically showed congestion and early fibrosis.

When the inferior vena cava was opened a large organized thrombus, measuring five cm. in length and three cms. in diameter, was seen to originate in the left hepatic vein. The large bulbous tail of this thrombus extended into the right atrium of the heart (Figure 1).

The right lobe of the liver was fibrotic and small. The left lobe was markedly enlarged and severely congested; most of the large hepatic veins were filled with thrombi (Figure 2). The gallbladder and the common bile duct were normal. No gallstones were found. On microscopic examination the left lobe of the liver showed marked congestion with distorted parenchyma in the region of the central veins and organized thrombi in the larger veins (Figures 3 and 4). The right lobe of the liver showed extensive necrosis with fibrous tissue replacement (Figure 5).

The sections of bone marrow were compatible with polycythemia vera, exhibiting a marked hyperplasia of the myeloid and erythroid elements with a myeloid-erythroid ratio of 2:1.

Discussion

The appearance of the bone marrow was typical of polycythemia vera and the peripheral blood counts and reticulocyte count remained elevated. Unfortunately, blood volume studies were not performed.

The complete destruction of the lobular histology with extensive fibrosis of the right lobe of the liver indicates that right hepatic vein occlusion most likely occurred some months prior to the terminal illness (early recanalization of the occluded right hepatic veins was seen). Subsequent obstruction of the main left hepatic vein by thrombus produced severe liver failure and ascites,

and extension of this thrombus to obstruct the inferior vena cava resulted in anasarca of the lower body. Oliguria, hyperkalemia, and azotemia followed, although the kidneys were anatomically normal at autopsy.

Hepatic vein thrombosis was first described by Budd¹ in 1845, and fifty years later Chiari² described hepatic endophlebitis. The presence of Budd-Chiari syndrome can be confirmed by inferior vena cava and hepatic venograms.³ Liver scan shows diminished and irregular uptake, similar to that in advanced cirrhosis, with increased splenic and bone marrow uptake. Parker⁴ studied 49 cases of autopsy-proven symptomatic hepatic vein occlusion and found that polycythemia vera was the most common underlying disorder (Table 1). Sohval⁵ has also described hepatic vein thrombosis in polycythemia vera. Hypernephroma is the next most common disorder. Other recently described causes of hepatic vein occlusion are oral contraceptives,^{6,7} membranous obstruction of

the inferior vena cava⁸ and *Aspergillus* hyphae in patients with acute leukemia.⁹

Therapy of the Budd-Chiari syndrome is largely symptomatic, with specific therapy directed at the underlying cause.

Fig. 5—Right lobe of liver: Fibrous replacement of liver cells with intact bile ducts (hematoxylin and eosin X 40).

Venereal Disease

To begin with, there was this strange fact; though the infection was there, the moon had often four times circled the earth before clear symptoms of the disease appeared. For when it has once been received into the body it does not immediately declare itself; rather it lies dormant for a certain time and gradually gains strength as it feeds. Meanwhile, however, the sufferers, weighed down by strange heaviness and irresistible langour, are going through life with increasing weakness, moving sluggishly in every limb. Their eyes, too, have lost their natural keenness; the colour is driven from their faces and deserts their unhappy brows.—Ghirolamo Fracastoro (1483-1553)

The Anxiety-Ridden Patient in Office Practice

PHILIP MARGOLIS, M.D.

ANXIETY ACTUALLY is helpful to many people. It is a warning that something may be wrong. Its development is the result of a conflict or problem often triggered by a difficult situation whereby an external stress stimulates internal stresses. Anxiety often manifests itself in physical symptoms which can lead the patient to seek help from his doctor. He usually has a positive trustful image of his doctor as a man who understands him and from whom he may obtain relief. Thus positive rapport is built in and the doctor is in a good position to assist the patient.

The physician listens to the patient and allows him to ventilate his concerns. He does a careful physical examination, which is generally negative, and the results are reassuring to the patient. The anxiety is relieved by the ministrations of the physician—by his listening, by his actions, and by his reassurance.

Often only one or two visits are necessary, plus or minus several phone calls at which time the physician makes himself available for a few minutes—the telephone has been underestimated as a therapeutic tool.

Thus a combination of support (which includes the examination), the encouragement of catharsis, the occasional use of drugs, and (perhaps) some authoritarian advice around a real-life situation, i.e., environmental manipulation) make up the therapeutic operations of the physician on behalf of the patient having anxiety symptoms.

The majority of anxious patients are handled successfully in the office. The important point is to pay full attention to the patient during the history taking which includes a mental status evaluation. The doctor is interested in what the patient wants to talk about, avoiding arguments and severe judgements. He encourages the patient to

talk *during* the physical examination (“What I’m really scared to death about is that I might have cancer”), reassures (“I understand how you feel. This is a common problem.”), utilizes suggestion (“These pills will give you a good night’s sleep.”), may be educative (“Let’s talk about what happens during the sex act.”), gives guidance and advice (“It sounds like this job would be worthwhile.”)

Listening is “trump”; when in doubt, play “trump” and, even if you don’t understand and one can’t always, listen anyway. A story is told about Dr. Helena Deutsch, a psychoanalyst in Boston, during a period when she was living in a hotel after she first came to the United States from Vienna. A room clerk, having heard of her skills, sought an interview with her to talk over some problems. Years later she met him and he told her that she had “helped him to clear up his difficulties completely.” The punch line of the story is this: At the time of the interview she had had great difficulty in understanding his English. But—she listened.

Environmental modification may be surprisingly helpful. One parent was extremely anxious because her child was in the hospital for a routine tonsillectomy but she wasn’t allowed to visit. Allow parents to visit their children in the hospital. A woman who resented her feminine role (“women’s lib?”) as a housewife was encouraged to get a job and hire a housekeeper to take care of the children. A lonely, elderly patient was helped to find appropriate social and recreational outlets—the physician should be aware of community resources. An anxious father and an anxious mother brought their even more anxious child to a pediatrician who quickly discovered that the child—age five—had been sleeping in his parent’s room all of his life. It was quickly pointed out in an authoritarian way that removing the child from the bedroom would be most helpful to all concerned. It was.

Let us suppose that on completion of the history and physical examination a patient is believed

Presented at the Minnesota Academy of Family Physicians’ Annual Refresher, April 5, 1972, Bloomington, Minnesota.

Dr. Margolis is Professor of Psychiatry, University of Michigan Medical Center, and Professor of Community Mental Health, Ann Arbor, Michigan.

to be suffering primarily from an anxiety reaction or psychogenic cardiovascular reaction. What next? "... 'Mr. Jones, after a thorough examination I do not believe you have any serious heart disease, although you have suffered from distressing chest pain and are naturally concerned about it. The pounding and skipping of your heart, I believe, results from a nervous reaction rather than from disease in your heart. For instance, if you walked down a dark alley at night and a masked bandit suddenly stuck a gun in your ribs, I am sure your heart would beat very fast and hard—not because it was bad, but in response to the nerve impulse that went out because of the fear you were experiencing. Your breath would also come short and fast and your hands would be wet and shaking as they were when you came into the office. Prolonged worry, tension, anger, or anxiety can produce the same nervous impulse as intense fear. That this is probably a factor in your case is suggested by the appearance of your symptoms shortly after the arrival of the new foreman with whom you are having trouble . . . You are afraid that your heart is bad, and as a double check I suggest we get an electrocardiogram, chest Xray, blood test and urinalysis as a part of a complete medical evaluation. I expect they will be normal. Even if they aren't, I am sure most of your symptoms result from nervous causes since no form of heart trouble can completely explain your symptoms while a tension state readily can.'"

It is important that a positive diagnosis be made before doing the laboratory studies—the physician thus shows confidence in his diagnosis. As each normal laboratory study is reported, the patient's confidence in the physician is increased. If he orders extensive laboratory studies without telling the patient he expects them to be negative, with each normal finding the patient's esteem for the physician will drop. The patient assumes the tests were ordered to find out what was wrong. When the physician finally tells the patient his symptoms are due to nervous factors, it appears he is saying this because he has been unable to find anything abnormal with the tests. To the patient, it looks like an alibi, his confidence in the doctor is shaken, and the usual story is for him to consult a different physician who, too often, 'does some different tests'.¹¹

Anxiety may accompany depression and may even help create a suicidal state. If indeed the pa-

tient is overwhelmed by his anxiety, if he manifests a panic reaction which does not appear to respond to the above procedures, hospitalization—either in a medical or psychiatric ward (preferably of a general hospital) is recommended. If the anxiety is accompanied by serious suicidal/homicidal thoughts, or evidence of a reality breakdown or confusional (possibly organic) symptomatology, placing the patient in the hospital is the treatment of choice.

If the patient presents a puzzle, i.e., if some of the causes of anxiety are unknown and if the patient is not responsive to initial help, the doctor is well advised to seek a consultation from a psychiatrist; the patient may be temporarily referred, not for treatment, but for consultation. A consultation is really evidence of continuing concern on the part of the physician, not a wish to avoid further contacts. The physician maintains interest in the patient but is simply in doubt about the diagnosis or treatment plan. If the physician is uncertain as to whether the patient is suicidal/homicidal, if he wants to clarify a possible delusional content of the patient's thought processes, if the patient exhibits a behavior disorder (e.g., peeping tom), of very recent onset, the doctor may wish to obtain advice from a mental health consultant. Sometimes the psychiatrist will wish to see the patient; at other times a telephone conversation or personal get-together between physicians will suffice.

In some cases a referral for psychiatric treatment is both necessary and appropriate. Anxiety comes in many forms, including a conversion reaction, a phobic reaction, a severe anxiety neurosis, and the like. Sometimes the physician is confronted with a moderate to severe psychophysiologic reaction (peptic ulcer, neurodermatitis, etc.) and he may wish to treat the ulcer medically while a psychiatrist treats the neurosis.

If a referral is contemplated, be straightforward and frank about the reasons for the referral. Place a referral in the same light as a referral to any other specialist. It is important, incidentally, to consult with the psychiatrist before broaching referral to the patient. The patient may object. He may say that psychiatrists treat only the insane. It is well to point out that indeed psychiatrists treat people who are emotionally upset and that the patient is definitely not insane. The patient may say "I don't know this new man." It is true the transition may be difficult, but the doctor must

indicate that he is not deserting the patient but is acting as a continuing central management agent or coordinator. The patient may not wish to lose his organic tag. In other words he may want to continue to think that his problems are all "medical-physical." However, if you wish to make a referral you must stand firm rather than saying, "Okay, we'll try vitamins for awhile on the chance that it might be a vitamin deficiency." Hypochondriasis is a way (among others) of channelling anxiety. Hypochondriacal symptoms are treatable—perhaps over an extended period of time—by the general physician. In fact, the hypochondriac is chronically ill. However, periodic visits to his physician—once a month or even less often—will maintain the hypochondriac, diminish his symptoms (at least temporarily), keep him functioning, and even keep him happy. The relationship with the physician, the physical examination and laboratory studies, and a judicious change of medication will insure a functional cure if not a symptomatic one. The hypochondriac relates through his symptoms which must be respected though not encouraged.

Finally, some general practitioners may have the time, energy, the skills, and the interest to do crisis intervention—brief psychotherapy.

An individual (or family) is in crisis when an immediate stress situation interferes with previous coping or problem-solving capacities to handle the situation and to come up with a solution. As Caplan says, it is a "time-limited period of psychological disequilibrium." There are all types of crises including those that involve a role transition (pregnancy) and those which involve hazardous events or chance happenings (illness, death). A crisis is a threat, a loss, or a challenge out of which a variety of emotional signs and symptoms may emerge. During a crisis, anxiety may be the most prominent symptom and the doctor who is often the "family friend" is usually the first person to whom he will turn. There is urgency about a crisis that makes a person unusually receptive to guidance and assistance. In fact, a crisis presents an optimal therapeutic moment due to the individual's readiness to seek and to respond to help.

Crisis intervention requires one to 10 sessions. During the course of treatment the physician utilizes a variety of plausible intervening techniques—clarifying feelings, outlining consequences of behavior, gently confronting the patient with real-

ity, appraising the patient's accomplishments (assets and liabilities), giving advice and reassurance. Exercising authority, making suggestions, setting time limits in advance, focusing on specific issues—all these methods are fair game to be flexibly employed. Termination is accomplished when symptoms are relieved and the patient is able to handle the current situation. In essence brief therapy then is goal-limited and problem-oriented. The physician is a listener but may also be active. He expects the patient to improve rapidly, at least as far as his symptoms are concerned. The thesis of crisis intervention is that for many patients therapy may stop after specific resolution or may act as a prelude to further treatment. For many, it is further treatment.

One example will suffice. Mrs. B. is a young woman, currently separated from her husband. Her chief complaint was a severe and constant anxiety, accompanied by palpitations. Past history included the death of her father eight years previously, the recent remarriage of her mother, and frequent hospitalizations for rheumatic carditis and congestive heart failure. Therapy consisted of four visits, at which time the origins of her anxiety were defined, "sorted out" and discussed. The origins centered around her "heart" difficulties, (e.g., her father had died of heart disease); some "grief work" was accomplished regarding her father's death and the failure of her marriage. Some concerns about her sexual drives and herself as a divorcee were analyzed. Clarification and support were given, directed to feelings of inferiority, stemming back to adolescence. Mrs. B. became asymptomatic; she has since obtained a divorce and has a satisfying job.

General physicians should be able to treat the milder anxiety conditions of recent onset. Some of the more chronic emotional conditions if not involving any active risk probably can be handled better in a palliative, supportive way by a general physician than by a psychiatrist. The most common error in psychiatric referral by general physicians is to refer the chronic hopeless cases who can only be supported and to hang on too long to moderately severe psychoneurotic patients who might be cured by intensive psychiatric treatment. If there is a good working arrangement with a psychiatrist, the borderline patients can be seen by him and returned to the general physician who continues supportive treatment in accordance with specialized advice.

Let's compare the anxiety-ridden patient with the patient who actually has heart disease. There are three methods of treatment: (1) Adaptation—the physician strengthens the conscious, adaptive functions of the personality via psychological support. He restores emotional homeostasis. With the heart patient he prescribes rest, medication, and diet. (2) A reduction of environmental stress—The physician uses environmental modi-

fication and manipulation, thereby alleviating the patient's anxiety. For the heart patient he prescribes a first-floor apartment rather than a third-floor walk-up. (3) Structural change—The physician usually refers the anxiety patient to a psychiatrist for intensive psychotherapy in order to define and to reduce internal (intrapsychic) pressures and conflicts. For the heart disease patients he may recommend cardiac surgery.

Dial Access Tapes

A new Dial Access Medical Tape has been added—Tape #829, COLPOSCOPY—A KEY TO THE ABNORMAL PAP SMEAR, *Preston P. Williams, M.D., U. of M., Department of Obstetrics and Gynecology*.

This new 5-minute medical abstract covers the use of a low-power stereoscopic microscope for evaluating the uterine cervix from which has come an abnormal Pap smear.

A script of this new tape and any Minnesota Dial Access tapes is available by writing NRMP.

The new Dial Access phone #:

Metro: 373-1855

Outstate: 1-800-552-7210

Dial Access tapes are being revised continuously. The newly revised Minnesota Tapes are:

#811: PHENYLBUTAZONE IN THE RHEUMATIC DISORDERS, *John W. Worthington, M.D., Mayo Clinic, Rochester, Minnesota*

#377: MANAGEMENT OF VASCULAR HEADACHE MIGRAINE TYPE, *Douglas Rooke, M.D., Mayo Clinic, Rochester, Minnesota*.

#398: CANCER OF THE LARYNX—TREATMENT SELECTION, *Lawrence W. DeSanto, M.D., Mayo Clinic, Rochester, Minnesota*

#458: MANAGEMENT OF TESTICULAR CARCINOMA, *Richard G. Hahn, M.D., Mayo Clinic, Rochester, Minnesota*

If you wish a copy of the MMIS Directory listing all Dial Access Tapes, please contact Northlands RMP at 375 Jackson St., St. Paul, 55101.

LeRoy G. Berglund

Northlands Regional Medical Program

The Physician Associate Program of the University of Minnesota Medical School

STEPHEN NYE BARTON

THIS ANALYSIS of a year's experience as a Physician Associate summarizes the program as it evolved in Cloquet, Minnesota. In the discussion below it will become evident that the Physician Associate has opportunities unique to this program which are of benefit to himself, his adopted community, and the medical school. Programs of this nature are educational and will enhance the delivery of health care in the state.

The preceptors were Cloquet physicians R. R. and R. H. Puumala. The student gradually became the doctor with his own patient population. Further, the physician associate had the opportunity to see disease and the consequences to the family develop over an extended period of time.

Each month one member of the University of Minnesota Department of Family Practice and one member of a specialty area visited Cloquet to participate in a clinical conference presented by the physician associate and his preceptors. This encouraged communication between the larger university medical complex and the rural physicians while at the same time fostering continuing

medical education.

Total Care

The Puumala Clinic is the center for the practice of preventive medicine, screening, and family medicine. The student doctor learns that the office must not become a contest for maximum volume but must emphasize the total needs of the patient. A child enters the clinic with a sore throat bringing a mother who has sexual frustrations and is considering divorce. The child's father is at work driving a truck trying to feed the family. A clinic oriented to maximum volume might treat the sore throat and overlook the more significant problems. The Physician Associate must consider the mother, her husband, her children, grandparents, and others.

Comprehensive Care

The delivery of emergency or acute care includes the treatment of allergic reactions, the application of plaster casts or splints after reduction of common fractures, repair of lacerations, treatment of cardiac arrhythmias and congestive heart failure. The physician associate makes

Figure—From the left: Stephen Nye Barton, student doctor, Dr. Robert Mathog, professor in the specialty of ears, nose and throat, Dr. Reino Puumala and Dr. John Verby, professor in family practice at the U of M.

house calls on the terminally ill and elderly that are not able to visit the office. House calls are also made to study and treat a family in the home environment.

Rounds in nursing homes were made. Episodic care was also given. The student becomes aware of problems unique to the institutionalized geriatric population. The cost, the family concerns or lack of care, the patient's initial disorientation and gradual adjustment, the use of vocational rehabilitation, and the usefulness of physical therapy are just a few of the factors that can best be perceived over a period of one year. The author also did physical examinations for the retarded and mentally disturbed.

Hospital Rounds

Daily rounds are made at the hospital on ten to fifteen patients. Being the only student allows maximum contact with the preceptors, the staff, and other hospital personnel. The student does histories and physical examinations on new patients. A problem list and provisional diagnosis is made and reviewed by the preceptor. The initial treatment and tests are planned around a theme of minimum cost for effective unit of health care rather than attempting to maximize the amount of information without regard to cost.

Consultation and Referral

Consultation is held with the pathologist, and the radiologist as well as other members of the medical staff. Microscopic slides and laboratory tests were studied. Further, it was a privilege to visit the departments of pathology and radiology at St. Luke's hospital in Duluth for consultation. Cases are referred to major medical centers by the student and preceptor if they are beyond the scope of the Cloquet physicians. If a patient fails to recover the medical student attends the autopsy.

Surgery

After morning rounds the physician associate regularly assists in surgery. A typical day might include a cholecystectomy, appendectomy, hip pinning, hernia repair, or gastric resection. Emergency surgery included a ruptured spleen, torn liver, and contused pancreas.

The physician associate is exposed to an extensive oncology population and sees tumors of all organs from carcinoma of the tongue to lymphosarcoma of the rectum. Before surgery the student studies the anatomy, surgical technique, and the pre- and postoperative management of the care. By the end of the year a physician associate is able to diagnose many of the common surgical entities. The student admits the patient, writes the preoperative orders, with the close supervision of the preceptor performs or assists in the surgery, orders the postoperative care, and follows the patient out of the hospital to see him in the office at regular intervals. On occasion the student plays a strategic role. An emergency cesarean section is a case in point. Following the course of labor in a multipara a prolapsed cord was discovered by the author. After notifying the surgical anesthetist and nursing team on call to arrange for immediate action, the attending physician was called and a live baby was rescued within an hour. Thus, in the physician associate program the student progresses in responsibility as he demonstrates competency, but always has the preceptor for consultation and backup. In conclusion, a Physician Associate in a rural town can learn while helping to deliver medical care to the community.

Acknowledgments

Appreciation to Ricard R. Puumala, M.D. and Reino R. Puumala, M.D., my preceptors; To Jack Verby, M.D., for introducing me to the program; To John O'Leary, M.D., for encouragement throughout the year; To Joe Connolly, M.D., for suggesting I write this article.

Great truths are portions of the soul of man; great souls are portions of eternity.

Classified advertising rates are thirty (30) cents a word; minimum monthly charge \$7.50; key number, fifty (50) cents additional.

Replies to advertisements with key numbers should be mailed in care of Minnesota Medicine, 375 Jackson, St. Paul, Minn. 55101.

PLYMOUTH BAPTIST CHURCH trust bonds, 8% 8-year and 7% 5-year bonds, \$1,000 and \$500 denominations. Sold only by prospectus. Write 13030 47th Ave. N., Mpls., Minn., 55442; or phone 612-544-1888.

INTERNIST wanted to join three other Internists in Department of Internal Medicine in twenty man multispecialty group, including sizeable Department of Family Medicine, \$30,000.00 to start, partnership in two years, many fringe benefits, new clinic, new hospital to be started soon, city of 25,000 with clean air, no traffic problems, no street crime. Call or write H. P. Van Cleve, M.D., Austin Clinic, Austin, Minnesota 55912 (Telephone (507) 433-7351)

ASSOCIATE FOR AAFP member in professional corporation or expense and call sharing association. New clinic building in construction to serve three rural communities. Immediate partnership in corporation, if desired. All corporate benefits immediately. Located in beautiful Hiawatha Valley of southeastern Minnesota, 35 miles from Mayo Clinic and 55 miles from Gunderson Clinic. Contact R. L. Sauer, M.D., Root River Valley Medical Clinic LTD., Box 496, Preston, Minnesota 55965.

PSYCHIATRIC STAFF—Requirements of three year residency training to Board Certified. \$26,000 to \$36,300 depending upon qualifications. Dramatically beautiful, leisurely paced, cultural, summer and winter vacationland. Superb sailing, skiing, fishing. Resident theater. Near Interlochen National Music Camp. College. J.C.A.H. approved 1,400 bed psychiatric hospital. Three year psychiatric residency program. Excellent fringe benefits. Contact Philip B. Smith, M.D., Room 322, Traverse City State Hospital, Traverse City, Michigan 49684. An equal opportunity employer.

WAYZATA MEDICAL BUILDING OFFICE SUITES—Located in the fastest growing suburban area in the Twin Cities. We offer:

- Surrounding area of lakes, country clubs, woods, beautiful homes;
- Unsurpassed medical building facilities
- Fast growing area—high median family incomes
- Beautiful building—inside and out
- Inner courtyard with trees and landscaping
- Heated indoor parking
- Adjacent access to freeway system
- Low rental rates—favorable base terms
- Financial services

We have grown to fourteen specialties since our building was completed two years ago. We particularly are interested in Orthopedics, Psychiatry, Urology, Otolaryngology, Internal Medicine and Dentistry. Give us a call. We have a lot more to show you and to talk about. Reply to: Mr. Paske, Wayzata Medical Building, 250 North Central Avenue, Wayzata, Minn. 55391, (612) 473-0031.

AN OPPORTUNITY to work with a 13 man group, seeking general practitioner, certified or board eligible urologist, orthopedic surgeon, ENT and 2 pediatricians; ideal location, clean northern Minnesota city, ample hunting, fishing, also cultural events sponsored by college with 5M students; unlimited lake shore home sites. Contact D. E. Carlson, Mgr., Bemidji Clinic, Ltd., Bemidji, MN 56601

GENERAL PRACTITIONER desired for northern Minnesota clinic located near Lake of the Woods area. Enjoy the clean air, clear waters, compatible working arrangements including ample time off for meetings, vacations and good financial arrangements. Excellently equipped hospital (acute, skilled nursing and board and care facilities). Fine clinic one block from hospital. Write: MINNESOTA MEDICINE, 473, 375 Jackson St., St. Paul 55101.

ASSOCIATES WANTED: Family doctors to join a growing Family Practice Department in a large multiple specialty medical center, Minneapolis suburb. Excellent opportunity for teaching undergraduate and graduate students in Family Practice. Four man department with excellent growth potential. Reply to Dr. Harley J. Racer, Chairman Family Practice Department, St. Louis Park Medical Center, St. Louis Park, MN 55416. Telephone 612-927-3320.

ST. CLOUD, MINNESOTA—Psychiatrists needed for Psychiatric Service, VA Hospital. Unit System, with a variety of therapeutic approaches. Growing Outpatient Service. Fully staffed and newly equipped TV studio and hospital-wide CCTV network available for creative ideas to therapy, education and research. Training affiliations in social work, psychology, nursing, occupational therapy. Three local colleges with many cultural and educational advantages. License in any state accepted. Financial assistance in moving. Liberal vacation, sick and health benefits. Excellent retirement plan. Salary dependent on professional qualifications. Nondiscrimination in employment. Write or phone collect: Chief of Staff, 612-252-1670.

WANTED: PHYSICIAN, WISHEK, NORTH DAKOTA—Wishek population—1400 plus 5000 surrounding area. 32 bed modern Hospital, 87 bed new Nursing Home. Hospital Board owns new \$35,000.00 home to be given to Physician rent free for 6 months; thereafter, reasonable rent. Free Clinic for 6 months; thereafter, rent reasonable. Hospital Board owns all Clinic equipment and instruments plus Xray Machine. Present Physician left Wishek to finish Surgical Residency. New 12 grade Public School System open Fall, 1972. Wishek is located in south central North Dakota. City Civic Center Auditorium. Green Lake is 12 miles from Wishek for good fishing, boating and lake lots. City outdoor heated Swimming Pool with tennis courts. Modern Park Facilities. 9-hole Golf Course with Club House. For further information contact: Eugene Wiest, Mayor, Wishek, North Dakota, Telephone 452-2255.

T₄ IS THE PREDICTABLE HORMONE BECAUSE IT LOVES PROTEIN.

ALL THYROID-FUNCTION TESTS ARE USEFUL IN MONITORING SYNTHROID THERAPY

TWO GOOD REASONS WHY THE ROAD TO NORMALIZED THYROID STATUS IS SO SMOOTH FOR THE SYNTHROID PATIENT

SYNTHROID® (sodium levothyroxine) is pure synthetic T₄, the major circulating thyroid hormone. It is reliable to use because of its affinity for protein-binding sites in the blood. T₃ is more fickle. Sometimes it binds. Sometimes it doesn't. T₄ more predictably binds to protein.

No calculations are needed, test interpretation is simple.

Any of the commonly used T₄ thyroid function tests (P.B.I., T₄ By Column, Murphy-Pattee, Free Thyroxine) are useful in monitoring patients on T₄ because they all measure T₄. Patients on SYNTHROID are thereby easy to monitor because their results will fall within predictable, elevated test ranges. Of course, clinical assessment is the best criterion of the thyroid status of the drug-treated patient.

(1) The onset of action of T₄ is gradual. It has a long in vivo "half-life" of over six days. (Occasional missed doses or accidental double-doses are of concern because of this factor.) (2) since SYNTHROID contains only T₄, the potential for metabolic surges traceable to more potent iodides (T₃) is eliminated.

TEST	HYPOTHYROID	SYNTHROID THERAPEUTIC NORMAL
P.B.I.	Less than 4 mcg %	6-10 mcg %
T ₄ By Column	Less than 3 mcg %	7-9 mcg %
T ₃ (Resin)	Less than 25%	27-35%
T ₃ (Red Cell)	Less than 11%	11.5-18%
Free Thyroxine	Less than 0.7 nanograms %	0.7-2.5 nanograms %
Murphy-Pattee	Less than 2.9 mcg %	4-11 mcg %

AS WITH ANY THYROID PREPARATION, CAUTIOUS OBSERVATION OF THE PATIENT DURING THE BEGINNING OF THERAPY WILL ALERT THE PHYSICIAN TO ANY UNTOWARD EFFECTS.

Side effects, when they do occur, are related to excessive dosage. Caution should be exercised in administering the drug to patients with cardiovascular disease. Read the accompanying prescribing information for additional data or write Flint Laboratories.

Choose the Smooth Road...to thyroid replacement therapy

PATIENTS CAN BE SUCCESSFULLY MAINTAINED ON A DRUG CONTAINING THYROXINE ALONE.

Thyroxine (T_4) is, as you know, the major circulating hormone produced by the thyroid gland. It is also produced, in smaller amounts, and is active at the cellular level. For years it has been a working hypothesis among endocrinologists that T_4 is converted by the body to T_3 . In 1970 this process, called "iodination," was demonstrated by Braverman, Ingbar, and Sterling². T_4 does convert to T_3 , though the precise quantities are still being studied.

The conversion has been experimentally demonstrated during the administration of T_4 to athyrotic patients. Their thyroid status is normalized on SYNTHROID alone, but the presence of T_3 in these patients has been clearly shown.

WHY DOES SYNTHROID COST LESS THAN SYNTHETIC DRUGS CONTAINING T_3 ?

Very simple. T_3 costs more to make synthetically than does T_4 . So it is economically necessary for a synthetic thyroid medication containing T_3 to cost more than one containing T_4 alone. Synthetic combinations cost patients nearly 50% more than SYNTHROID³ because the T_3 costs more to start with; also there is the additional expense of formulating a tablet containing two active ingredients.

Synthroid[®]

(sodium levothyroxine)

THE FACTS ARE CLEAR AND HERE IS OUR OFFER.

FACTS:

Synthetic thyroid drugs are an improvement over animal gland products. Patients, even athyrotic ones, can be completely maintained on SYNTHROID (T_4) alone. Thyroid function tests are easy to interpret since they are predictably elevated when the patient adheres to SYNTHROID. Of all synthetic thyroid drugs, SYNTHROID is the most economical to the patient.

OFFER:

Free TAB-MINDER medication dispensers to start or convert all your hypothyroid patients to SYNTHROID. Free information to physicians on role of thyroid function tests in a new booklet titled: "Guideposts to Thyroid Therapy." Ask us.

Specific replacement therapy for diminished or absent thyroid function resulting from primary or secondary atrophy of the gland, congenital defect, surgery, excessive radiation, or antithyroid drugs. Indications for SYNTHROID (sodium levothyroxine) Tablets include myxedema, hypothyroidism without myxedema, hypothyroidism in pregnancy, pediatric and geriatric hypothyroidism, hypopituitary hypothyroidism, simple (nontoxic) goiter, and reproductive disorders associated with hypothyroidism. SYNTHROID (sodium levothyroxine) for Injection is indicated for intravenous use in myxedematous coma and other thyroid dysfunctions where rapid replacement of the hormone is required. The injection is also indicated for intramuscular use in cases where the oral route is suspect or contraindicated due to existing conditions or to absorption defects, and when a rapid onset of effect is not desired.

Precautions: As with other thyroid preparations, an overdose may cause diarrhea or cramps, nervousness, tremors, tachycardia, vomiting and continued weight loss. These effects may begin after four or five days or may not become apparent for one to three weeks. Patients receiving the drug should be observed closely for signs of thyrotoxicosis. If indications of overdose appear, discontinue medication for 2-6 days, then resume at a lower dosage level. In patients with diabetes mellitus, careful observations should be made for changes in insulin or other antidiabetic drug dosage requirements. If hypothyroidism is accompanied by adrenal insufficiency, as Addison's Disease (chronic subcortical insufficiency), Simmonds's Disease (panhypopituitarism) or Cushing's syndrome (hyperadrenalism), these dysfunctions must be corrected prior to and during SYNTHROID (sodium levothyroxine) administration. The drug should be administered with caution to patients with cardiovascular disease; development of chest pains or other aggravations of cardiovascular disease requires a reduction in dosage.

Contraindications: Thyrotoxicosis, acute myocardial infarction. **Side effects:** The effects of SYNTHROID (sodium levothyroxine) therapy are slow in being manifested. Side effects, when they do occur, are secondary to increased rates of body metabolism; sweating, heart palpitations with or without pain, leg cramps, and weight loss. Diarrhea, vomiting, and nervousness have also been observed. Myxedematous patients with heart disease have died from abrupt increases in dosage of thyroid drugs. Careful observation of the patient during the beginning of any thyroid therapy will alert the physician to any untoward effects.

In most cases with side effects, a reduction of dosage followed by a more gradual adjustment upward will result in a more accurate indication of the patient's dosage requirements without the appearance of side effects.

Dosage and Administration: The activity of a 0.1 mg. SYNTHROID (sodium levothyroxine) TABLET is equivalent to approximately one grain thyroid, U.S.P. Administer SYNTHROID tablets as a single daily dose, preferably after breakfast. In hypothyroidism without myxedema, the usual initial adult dose is 0.1 mg. daily, and may be increased by 0.1 mg. every 30 days until proper metabolic balance is attained. Clinical evaluation should be made monthly and PBI measurements about every 90 days. Final maintenance dosage will usually range from 0.2-0.4 mg. daily. In adult myxedema, starting dose should be 0.025 mg. daily. The dose may be increased to 0.05 mg. after two weeks and to 0.1 mg. at the end of a second two weeks. The daily dose may be further increased at two-month intervals by 0.1 mg. until the optimum maintenance dose is reached (0.1-1.0 mg. daily).

Supplied: Tablets: 0.025 mg., 0.05 mg., 0.1 mg., 0.15 mg., 0.2 mg., 0.3 mg., 0.5 mg., scored and color-coded, in bottles of 100, 500, and 1000. Injection: 500 mcg. lyophilized active ingredient and 10 mg. of Mannitol, N.F., in 10 ml. single-dose vial, with 5 ml. vial of Sodium Chloride Injection, U.S.P., as a diluent. SYNTHROID (sodium levothyroxine) for Injection may be administered intravenously utilizing 200-400 mcg. of a solution containing 100 mcg. per ml. If significant improvement is not shown the following day, a repeat injection of 100-200 mcg. may be given.

It's about time somebody told the true story of the American Doctor

You'd agree 100% on that. There have been too many of the other kind of story.

You know that the vast majority of American doctors are honest, hardworking, skilled and dedicated human beings who have the interests of their patients at heart.

That's exactly what the AMA is trying to make the public aware of.

One of the many ways the AMA is doing it is through its special communications program.

Perhaps you've seen pages in newspapers and national magazines signed "America's Doctors of Medicine." They're part of this program. It tells the true story of what it takes to become a doctor. The ways American medicine has improved the public's health. And to express the profession's concern about health by providing information which will help every American lead a healthier life.

We're telling this story for you, the American doctor. If we are to continue to represent you effectively, we need your support.

Find out more about what the AMA does for you and the public. Send for the pamphlet, "The AMA and the American Doctor: Sharing a Common Goal." Write: Dept. DW, at the address below.

History

Lafayette Houghton Bunnell. M.D.

of Homer, Minnesota

Discoverer of the Yosemite

EDWARD E. HARNAGEL, M.D.

MEDICINE HAS contributed many explorers and adventurers—Thomas Dover, Mungo Park, David Livingston, Marcus Whitman, Wilfred Grenfell are but a few of these. In contemporary times three of the 19 members of the 1963 Mt. Everest expedition were physicians; one of the six who reached the summit was an anesthesiologist. Pioneer physicians in impressive numbers explored the vast wilderness regions of this country and recorded their findings in logs, journals, memoirs and books. One of these was Dr. Lafayette Houghton Bunnell, a practitioner for many years in Homer, Minnesota, a tiny hamlet on the Mississippi a few miles south of Winona. He received scant recognition during his life for an exploratory venture in his youth, the discovery of one of the world's great natural wonders, the magnificent Yosemite Valley of California. He selected its name and names of many of its peaks and waterfalls, and left behind a vivid account of this natural wonder, its discovery and its original inhabitants.

He was born in Rochester, New York in 1824. When he was nine years of age, his physician father moved the family to the Michigan Territory and settled in the little French-Indian trading village of Detroit. His mother's cousin, Douglas Houghton, M.D., was a practicing physician in Detroit and a botanist, explorer and geologist of note. Bunnell grew up among the Chippewa Indians, learning to hunt and fish, swim, skate and fight with them and to speak their tongue. After a few years of elementary education, he worked for sometime in a drug store and then somewhat against his own will, went into his father's office. It is said that he attended private clinics and demonstrations. He soon found books and routine office chores confining and boring. From intimate acquaintance with French and Indian traders, soldiers and frontiersmen, he became infected with the romantic notion of going West.

His first westward venture, when he was 16 or 17 years of age, was with an older brother,

Willard, on a trip to the upper Mississippi Valley. Here, near the present site of La Crosse, Wisconsin, he engaged in fishing and lumbering for two years. He became interested in the Winnebago Indians of the area and learned their language and also learned much of the fauna and flora, natural history and geography of the area, which he related some years later in his book on Winona County. He returned to Detroit after several years, and recommenced the study of medicine as a preceptee of a Dr. Scoville. In 1846 Bunnell served in the Mexican War as a hospital steward and for a brief time, was in charge of a field hospital.

He was captivated by the news of the discovery of gold in California and traveled overland from Mexico to Mariposa, California, in 1849. It is assumed that he staked out claims and worked in

L. H. Bunnell

Fig. 1—Frontispiece of L. H. Bunnell. (1490 Bunnell, L. H. Discovery of the Yosemite. Chicago, 1880. Reproduced by permission of The Huntington Library, San Marino, California.)

Los Angeles, California.
See editorial, page 44.

the gold fields.

In 1851 Bunnell became a member of the Mariposa Battalion, a vigilante group of about 200 organized by the United States Indian Commissioner to subdue marauding Indians. Historians of this period indicate that this action was "necessary" because of the numerous Indian "depredations" on miners and settlers. Viewed from a century's vantage point, it seems probable that the California Indians, a generally timid and peaceful group, were more frequently victims than aggressors in their dealings with the white interlopers. Most San Joaquin Valley Indians were rather easily persuaded by the Mariposa Battalion to come onto a reservation near Fresno on threat of death and the destruction of all their property. However, the Grizzly Bear or Yosemite Tribe which came down from a mountain stronghold on a few occasions to attack farms and trading posts was not so submissive. Therefore, in the Spring of 1851 Indian runners were sent out from the battalion's encampment on the south fork of the Merced River to tell the Yosemite Indians that, if they would come in and make a treaty with the Indian Commissioner, they would be furnished with food and clothing, but if they did not, war would be declared and they would all be annihilated. The old Chief of the Yosemite Indians, Tenaya, answered this ultimatum in person. He declared to Major Savage, the head of the Battalion:

"My people do not want anything from the

Great White Father you tell me about. The Great Spirit is our father and has supplied us with all we need. We do not want anything from the white man. Our squaws are able to do our work."

Although wishing to spurn this federal patrimony, Tenaya was convinced from previous experience that his people would indeed be destroyed by the Mariposa Battalion. He, therefore, returned to the mountains and, in a few days, led in a motley band of only 72 men, women and children. He stated that the remainder of the band, probably no more than 125, had fled over the mountains to the East to join the Mono or Tuolumne Tribes.

Major Savage, who did not believe the old Chief, decided to enter the mountain stronghold and round up the rest of the tribe. Ascending the Sierra Nevada by the old Mariposa Trail, the Battalion reached what is now known as Inspiration Point whence the magnificent valley with its majestic enclosing cliffs comes into full view. This sight was as overpowering to Bunnell as it has been to countless others since. He wrote:

"None but those who have visited this wonderful valley can imagine the feelings with which I looked upon the view which was here presented. The grandeur of the scene was softened by the haze which hung over the valley, light as gossamer and by clouds which partially obscured the higher cliffs and mountains. This obscurity of vision increased the awe with which I beheld it and as I looked, a peculiar exalted sensation seemed to fill my whole being and I found my eyes in tears with emotion . . . It seemed to me that I had entered

Fig. 2—General View of the Yosemite Valley. (352554 Hutchings, J. M. *Scenes of Wonder and Curiosity in California*. New York, 1870. Reproduced by permission of *The Huntington Library, San Marino, California*.)

God's holiest temple. There was assembled all that was most divine in material creation. For days afterward, I could think only of the magnificence, beauty and grace of the waterfalls and the mountain scenery; and almost total lack of appreciation of that on the part of Major Savage caused me to think him utterly void of sentiment."

After the Battalion had pitched camp, Bunnell decided a name should be given the valley. Names were proposed by members of the group, but none were suitable. Bunnell suggested that it would be most fitting to name the valley for the Indians who had lived there and were now being driven out. The name Yosemite was unanimously adopted. During the next three months, the Battalion explored the valley and many of its canyons but found few Indians. They did discover large caches of food, principally acorns, the staple of the Indian diet, and destroyed them. Bunnell learned much of the Yosemite's history, arts and crafts and especially their skill in basket weaving. He described their diet and methods of cooking and observed their sweat houses and burial customs. He learned that every peak, cliff, canyon, meadow, stream and valley had a distinctive name and made a considerable effort to record these in their native purity.

"I applied myself perseveringly to the task of preserving these names, for even at an early date, I realized that public interest would be attached to this wonderful locality. I was ridiculed for the idea, or at least for the supposition that it would, probably be awakened during my lifetime."

Many of the Indian names such as Too-lool-lo-weack for Nevada Falls, were overlong and clumsy and for these he suggested English equivalents or other appropriate names. Among those which he selected and which are still used are Yosemite, Nevada, and Vernal Falls; El Capitan, Half Dome, and Mirror Lake.

When the Mariposa Battalion was deactivated later in 1851, Dr. Bunnell remained in California for five years trading, mining and surveying. He

then returned to the East. He served in the Civil War, entering as a private and, through successive promotions, reaching the rank of Major. His appointment as a commissioned officer became possible after an honorary degree of medicine was conferred on him by the La Crosse Medical College, a short-lived institution.

After the war, he settled in Homer, Minnesota which had been founded by his brother, Willard, and named after his birthplace, Homer, New York. In contrast with the high adventure of his early years, the remaining three decades of his life were prosaic. It is known that he practiced medicine and was a student of botany and science. He contributed to the first history of Winona County written in 1883. As historian for the Winona County Settler's Association, he published "*Winona and Its Environs on the Mississippi in Modern and Ancient Days*," a volume of nearly seven hundred pages. He also contributed historical articles to newspapers and magazines. His most significant writing was *Discovery of the Yosemite*, which was first published in 1880 and which went through four editions, the last published posthumously in 1911. This is a lucid and fascinating account of his explorations and observations in the great valley, written nearly 30 years after the discovery.

An interesting footnote is that one of Bunnell's admirers was the renowned Johns Hopkins' gynecologist, Dr. Howard Kelly whose contention was that Dr. Bunnell should be considered the true discoverer of the Yosemite Valley:

"... he alone of the little group that entered on a punitive expedition went eager and thrilled with the zest of discovery. He fully appreciated the opportunity and was filled with a sense of mystery. His companions were impassive and unimpressed, while he was exulting in the glories that unfolded before them; he became its baptismal sponsor and gave the valley its euphonious name, and later wrote about it in a never-failing spirit of enthusiasm."

In serious gram-negative infections*

Simplified dosage guidelines

Usual adult dosage - - I.M. and I.V. - - in patients with normal renal function

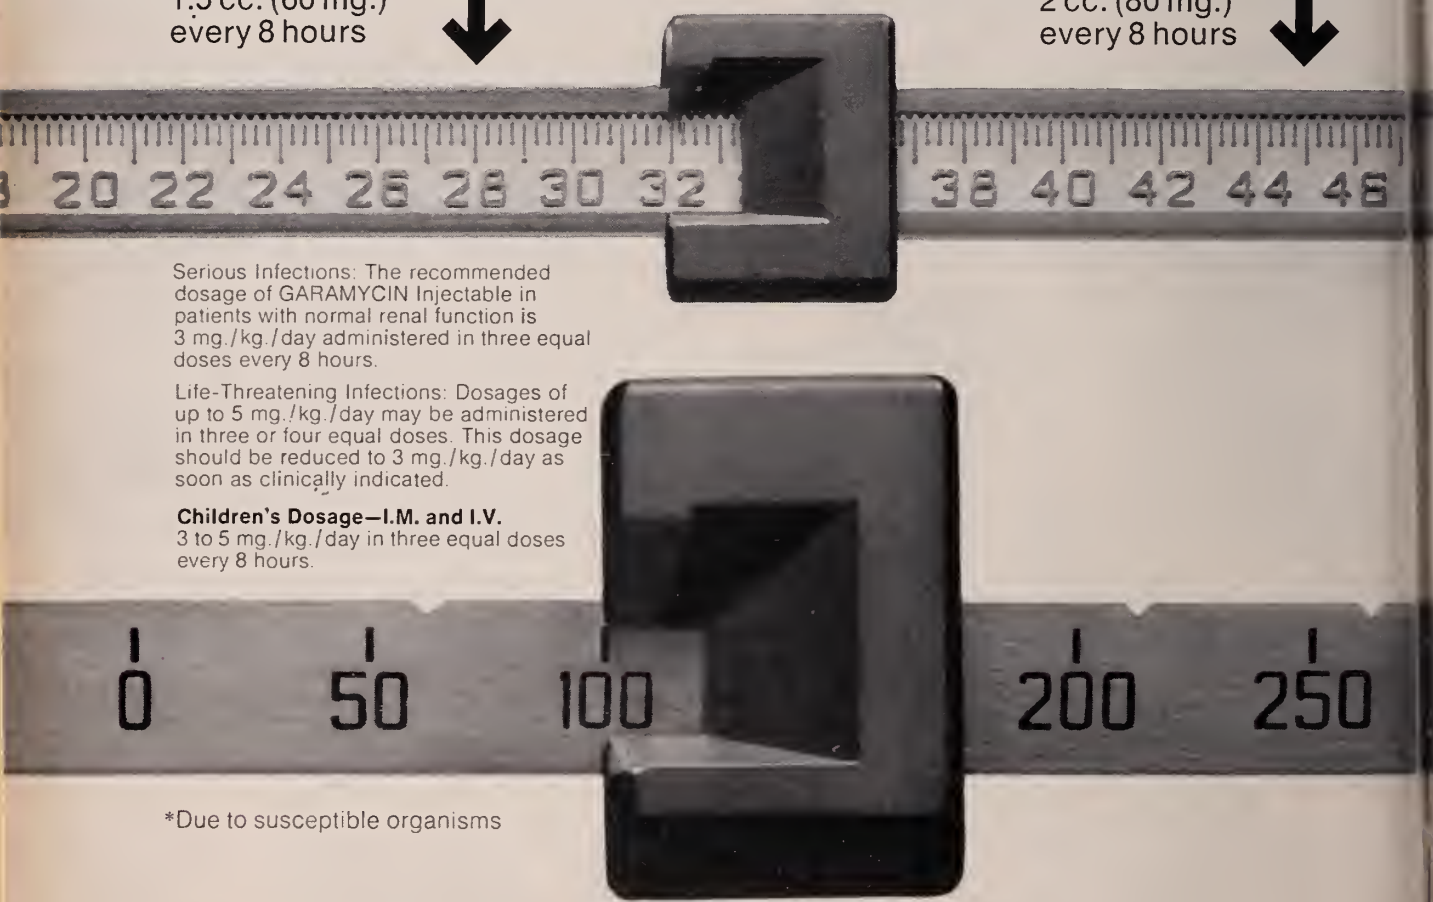

132 lbs. or less

1.5 cc. (60 mg.)
every 8 hours

Over 132 lbs.

2 cc. (80 mg.)
every 8 hours

Serious Infections: The recommended dosage of GARAMYCIN Injectable in patients with normal renal function is 3 mg./kg./day administered in three equal doses every 8 hours.

Life-Threatening Infections: Dosages of up to 5 mg./kg./day may be administered in three or four equal doses. This dosage should be reduced to 3 mg./kg./day as soon as clinically indicated.

Children's Dosage—I.M. and I.V.

3 to 5 mg./kg./day in three equal doses every 8 hours.

*Due to susceptible organisms

WARNING

Patients treated with GARAMYCIN Injectable should be under close clinical observation because of the potential toxicity associated with the use of this drug.

Ototoxicity, both vestibular and auditory, can occur in patients, primarily those with pre-existing renal damage, treated with GARAMYCIN Injectable, usually for longer periods or with higher doses than recommended.

GARAMYCIN Injectable is potentially nephrotoxic, and this should be kept in mind when it is used in patients with pre-existing renal impairment.

Monitoring of renal and eighth nerve function is recommended during therapy of patients with known impairment of renal function. This testing is also recommended in patients with normal renal function at onset of therapy who develop evidence of nitrogen retention (increasing BUN, NPN,

creatinine or oliguria). Evidence of ototoxicity requires dosage adjustments or discontinuance of the drug.

In event of overdose or toxic reaction peritoneal dialysis or hemodialysis will aid in removal of gentamicin from the blood.

Serum concentrations should be monitored when feasible and prolonged concentrations above 12 mcg./ml. should be avoided.

Concurrent use of other neurotoxic and/or nephrotoxic drugs, particularly streptomycin, should be avoided.

Garamycin[®]

gentamicin sulfate

injectable

I.M./I.V.

40 mg. per cc.

Each cc. contains gentamicin sulfate equivalent to 40 mg. gentamicin

Schering

Duration of therapy—I.M. and I.V.

The usual duration of treatment is 7 to 10 days. In difficult and complicated infections, a longer course of therapy may be necessary.

Instructions for I.V. use

Dilution—A single dose is diluted in 100 or 200 cc. of sterile normal saline or in a sterile solution of dextrose 5% in water; in infants and children, the volume of diluent should be less. The concentration of gentamicin in solution should not exceed 1 mg./cc. (0.1%).

Infusion time—The solution is infused over a period of 1 to 2 hours.

Premixing—GARAMYCIN Injectable should not be physically premixed with other drugs but should be administered separately in accordance with the recommended route of administration and dosage schedule.

In adults with impaired renal function

The single dose of GARAMYCIN Injectable given by patient weight remains the same; however, the interval between doses must be extended.

This interval may be approximated by multiplying the serum creatinine by eight as follows:

$$\text{Serum creatinine} \times 8 = \text{frequency of administration} \\ (\text{mg./100 ml.}) \quad (\text{in hours})$$

This dosage schedule is not intended as a rigid recommendation, but is provided as a guide to dosage when the measurement of gentamicin serum levels is not feasible.

See Clinical Considerations section which follows...

neomycin, kanamycin, cephaloridine, in, polymyxin B, and polymyxin E n), should be avoided. Concurrent use of gentamicin with po- retics should be avoided, since certain cs by themselves may cause ototoxic- addition, when administered intrave- diuretics may cause a rise in gentami- um level and potentiate neurotoxicity. E IN PREGNANCY Safety for use nancy has not been established.

Garamycin® Injectable
brand of gentamicin sulfate U.S.P., injection, 40 mg./cc.
Each cc. contains gentamicin sulfate equivalent to 40 mg. gentamicin
For Parenteral Administration

WARNING: Patients treated with GARAMYCIN Injectable should be under close clinical observation because of the potential toxicity associated with the use of this drug.

Ototoxicity, both vestibular and auditory, can occur in patients, primarily those with pre-existing renal damage, treated with GARAMYCIN Injectable, usually for longer periods or with higher doses than recommended.

GARAMYCIN Injectable is potentially nephrotoxic, and this should be kept in mind when it is used in patients with pre-existing renal impairment.

Monitoring of renal and eighth nerve function is recommended during therapy of patients with known impairment of renal function. This testing is also recommended in patients with normal renal function at onset of therapy who develop evidence of nitrogen retention (increasing BUN, NPN, creatinine or oliguria). Evidence of ototoxicity requires dosage adjustments or discontinuance of the drug.

In event of overdose or toxic reactions, peritoneal dialysis or hemodialysis will aid in removal of gentamicin from the blood.

Serum concentrations should be monitored when feasible and prolonged concentrations above 12 mcg./ml. should be avoided.

Concurrent use of other neurotoxic and/or nephrotoxic drugs, particularly streptomycin, neomycin, kanamycin, cephaloridine, viomycin, polymyxin B, and polymyxin E (colistin), should be avoided.

The concurrent use of gentamicin with potent diuretics should be avoided, since certain diuretics by themselves may cause toxicity. In addition, when administered intravenously, diuretics may cause a rise in gentamicin serum level and potentiate neurotoxicity.

USAGE IN PREGNANCY Safety for use in pregnancy has not been established.

INDICATIONS GARAMYCIN Injectable is indicated, with due regard for relative toxicity of antibiotics, in the treatment of serious infections caused by susceptible strains of the following microorganisms:

Pseudomonas aeruginosa, *Proteus* species (indole-positive and indole-negative), *Escherichia coli* and *Klebsiella-Enterobacter-Serratia* species.

Clinical studies have shown GARAMYCIN Injectable to be effective in septicemia and serious infections of the central nervous system (meningitis), urinary tract, respiratory tract, gastrointestinal tract, skin and soft tissue (including burns).

Bacteriologic tests to determine the causative organisms and their susceptibility to gentamicin should be performed.

Bacterial resistance to gentamicin develops slowly in stepwise fashion; there have been no one-step mutations to high resistance.

In suspected or documented gram-negative sepsis, GARAMYCIN may be considered as initial therapy. The decision to continue therapy with this drug should be based on the results of susceptibility tests, the severity of the infection, and the important additional concepts contained in the Warning Box. In the neonate with suspected sepsis or staphylococcal pneumonia, a penicillin type drug is usually indicated as concomitant antimicrobial therapy.

GARAMYCIN Injectable has been shown to be effective in serious staphylococcal infections. It may be considered in those infections when penicillins or other less potentially toxic drugs are contraindicated and bacterial susceptibility testing and clinical judgment indicate its use.

CONTRAINDICATIONS A history of hypersensitivity to gentamicin is a contraindication to its use.

WARNINGS See Warning Box.

PRECAUTIONS Neuromuscular blockade and respiratory paralysis have been reported in the cat receiving high doses (40 mg./kg.) of gentamicin. The possibility of these phenomena occurring in man should be considered if gentamicin is administered to patients receiving neuromuscular blocking agents such as succinylcholine and tubocurarine.

Treatment with gentamicin may result in overgrowth of nonsusceptible

organisms. If this occurs, appropriate therapy is indicated.

ADVERSE REACTIONS

Nephrotoxicity: Adverse renal effects, as demonstrated by rising BUN, NPN, serum creatinine and oliguria, have been reported. They occur more frequently in patients with a history of renal impairment treated with longer than recommended dosage.

Neurotoxicity: Adverse effects on both vestibular and auditory branches of the eighth nerve have been reported in patients on high dosage and/or prolonged therapy. Symptoms include dizziness, vertigo, tinnitus, roaring in the ears and hearing loss.

Numbness, skin tingling, muscle twitching, and convulsions have also been reported.

Note: The risk of toxic reactions is low in patients with normal renal function who do not receive GARAMYCIN Injectable at higher doses or for longer periods of time than recommended.

Other reported adverse reactions, possibly related to gentamicin, include increased serum transaminase (SGOT, SGPT), increased serum bilirubin, transient hepatomegaly, decreased serum calcium; splenomegaly, anemia, increased and decreased reticulocyte counts, granulocytopenia, thrombocytopenia, purpura; fever, rash, itching, urticaria, generalized burning, joint pain, laryngeal edema; nausea, vomiting, headache, increased salivation, lethargy and decreased appetite, weight loss, pulmonary fibrosis, hypotension and hypertension.

DOSAGE AND ADMINISTRATION GARAMYCIN Injectable may be given intramuscularly or intravenously.

For Intramuscular Administration:
PATIENTS WITH NORMAL RENAL FUNCTION*

Adults: The recommended dosage for GARAMYCIN Injectable for patients with serious infections and normal renal function is 3 mg./kg./day, administered in three equal doses every 8 hours.

For patients weighing over 60 kg. (132 lb.), the usual dosage is 80 mg. (2 cc.) three times daily. For patients weighing 60 kg. (132 lb.) or less, the usual dose is 60 mg. (1.5 cc.) three times daily.

In patients with life-threatening infections, dosages up to 5 mg./kg./day may be administered in three or four equal doses. This dosage should be reduced to 3 mg./kg./day as soon as clinically indicated.

*In children and infants, the newborn, and patients with impaired renal function, dosage must be adjusted in accordance with instructions set forth in the Package Insert.

For Intravenous Administration:

The intravenous administration of GARAMYCIN Injectable is recommended in those circumstances when the intramuscular route is not feasible (e.g., patients in shock, with hematologic disorders, with severe burns, or with reduced muscle mass).

For intravenous administration, in adults, a single dose of GARAMYCIN Injectable may be diluted in 100 or 200 cc. of sterile normal saline or in a sterile solution of dextrose 5% in water; in infants and children, the volume of diluent should be less. The concentration of gentamicin in solution, in both instances should normally not exceed 1 mg./cc. (0.1%). The solution is infused over a period of 1 to 2 hours.

The recommended dose for intravenous administration is identical to that recommended for intramuscular use.

GARAMYCIN Injectable should not be physically pre-mixed with other drugs, but should be administered separately in accordance with the recommended route of administration and dosage schedule.

HOW SUPPLIED GARAMYCIN Injectable, 40 mg. per cc., 2 cc. multiple-dose vials for parenteral administration.

Also available, GARAMYCIN Pediatric Injectable, 10 mg. per cc., 2 cc. multiple-dose vials for parenteral administration.

Book Reviews

DEATH AND ATTITUDES TOWARD DEATH. Proceedings of a Symposium held at the University of Minnesota. Edited by Stacey B. Day. Bell Museum of Pathology. 1972. \$1.00.

We are engaged in a lifelong struggle with the enemy, death, yet rarely do we take time to examine our adversary. Stacey Day has assembled a varied group to discuss death: physicians, a nurse, philosophers (including a professor of political science), scientists and clergymen. It is fascinating reading. The Symposium discusses many problems about death that most physicians tend to ignore but are important to the patient and his family. For instance should a patient be allowed to go home to die in his own bed if that is his desire? How can a man end his existence in dignity in a hospital bed with his every orifice cannulated, his excretions soiling his linen? There is little dignity in a hospital bed nor can there be. Ladies and gentlemen become simply men and women when they don the hospital gown. Death is not beautiful, B. J. Kennedy to the contrary notwithstanding. But it is not the worst of evils and in the terminally ill with no hope of recovery especially in the presence of suffering it is the only surcease available. These Proceedings have been bodily lifted from the panel podium. The questions craftily put by Day and the varied answers are stimulating. But the format leads inevitably to problems that might have been solved by judicious editing. I submit the question: "Mulford Sibley have you anything to say," and the answer: "No"—adds nothing.

Death is a great sounding board for Day's poetic questions. John Brantner summed it all up discussing a child's conception of his own death (no different from most adults): It is inconceivable.

Rueben Berman, M.D.
Minneapolis, Minnesota

SYNOPSIS OF PATHOLOGY, 8th Edition, by W. A. C. Anderson & T. M. Scotti, C. V. Mosby Co. \$13.95.

If you want to know what is meant by a cystadenofibroma of the ovary, it's here, in four clear, concise lines. Other subjects are treated similarly, sometimes at greater length, and often with nicely selected illustrations of gross and microscopic pathologic material. Despite its 1076 pages, the book is small, and in this age of bigger being equated with better, it is refreshing to see

that less can be best. This book may be the best for many phases of student teaching, and for practitioners who remove tissue and want a quick reference to round out knowledge of a disease process, since it covers more than surgical pathology. Recommended.

Robert L. Woodburn, M.D.
St. Paul, Minnesota

CURRENT PEDIATRIC DIAGNOSIS AND TREATMENT, Second Edition. Edited by C. H. Kempe, M.D., H. K. Silver, M.D., Donough O'Brian, M.D., F.R.C.P., et al. Pp 1008. Lange Medical Publishers, Los Altos, California, 1972. \$12.00.

The 7¼" x 10¼" x 1¼" size of this paperback precludes its use as a pocket reference. However, the effectiveness of presentation well offsets the disadvantage of bulkiness. It is the kind of volume that should be at fingertip as a quick reference resource on every pediatric hospital station, in clinics where children are being seen or in the young physician's office.

The sturdy construction should withstand average wear during the useful life implied by the little word "Current." On a busy pediatric station, replacement may be necessary before a newer edition is available.

Considering the large number of contributors, the editors are to be commended for the uniformly crisp, concise style found throughout the book. The comprehensive material is well indexed. The references listed at the end of each topic furnish a starting point for those who need to explore a subject in more detail. The generous sprinkling of tables adds to ready availability of information. These tables are well labeled and easily interpreted. Illustrations are used primarily to clarify diagnostic and therapeutic procedures.

One might take issue with some specifics of treatment which would need modification for individual cases. An experienced clinician has the background for making these adjustments which is not available to the novice who may tend to use this as a "cookbook." However, no book can be expected to compensate for all the foibles of human nature and the recommendations, in general, are good ones. I consider this book a very good buy in general pediatric resource material.

FEBRUARY 1973

"Nuclear Group"

Dorothy Bernstein, M.D.

Everybody experiences psychic tension.

Most people can handle this tension.

Some people develop excessive psychic tension and need your counseling,

and a few may need counseling
and the psychotropic action of Valium® (diazepam).

Before deciding to make Valium (diazepam) part of your treatment plan, check on whether or not the patient is presently taking drugs and, if so, what his response has been. Along with the medical and social history, this information can help you determine initial dosage, the possibility of side effects and the ultimate prospects of success or failure.

While Valium can be a most helpful adjunct to your counseling, it should be prescribed only as long as excessive psychic tension persists and should be discontinued when you decide it has accomplished its therapeutic task. In general, when dosage guidelines are followed, Valium is well tolerated (see Dosage). For convenience it is available in 2-mg, 5-mg and 10-mg tablets.

Drowsiness, fatigue and ataxia have been the most commonly reported side effects.

Until response is determined, patients receiving Valium should be cautioned against engaging in hazardous occupations requiring complete mental alertness, such as driving or operating machinery.

Roche Laboratories
Division of Hoffmann-La Roche Inc.
Nutley, N.J. 07110

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anti-convulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect.

Adults: Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. **Geriatric or debilitated patients:** 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) **Children:** 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 100 and 500. All strengths also available in Tel-E-Dose® packages of 1000.

He won't resist feeling better with **Mylanta[®]**

Because the taste is good.

- ☐ promptly relieves hyperacidity
- ☐ also relieves fullness and bloating
- ☐ non-constipating

LIQUID **MYLANTA[®]** TABLETS

aluminum and magnesium hydroxides with simethicone

STUART PHARMACEUTICALS | Division of ICI America Inc. | Wilmington, Del. 19899 | Pasadena, Calif. 91109

Why send him to the islets of Langerhans?

Since sulfonylureas promote the release of insulin which is lipogenic and helps transport glucose into adipose tissue...

And since many overweight patients already have normal or high levels of endogenous insulin, why not consider DBI-TD?

It lowers blood sugar without stimulating

insulin secretion from the pancreas. And this may be important to the dieting diabetic.

In adult-onset, nonketotic diabetics uncontrolled by diet alone...

DBI-TD[®] Geigy
phenformin HCl

lowers blood sugar without raising blood insulin.

DBI[®] phenformin HCl
Tablets of 25 mg.

DBI-TD[®] phenformin HCl
Timed-Disintegration

Capsules of 50 and 100 mg.

Indications: Stable adult diabetes mellitus; sulfonylurea failures, primary and secondary; adjunct to insulin therapy of unstable diabetes mellitus.

Contraindications: Diabetes mellitus that can be regulated by diet alone; juvenile diabetes mellitus that is uncomplicated and well regulated on insulin; acute complications of diabetes mellitus (metabolic acidosis, coma, infection, gangrene); during uremia; cardiovascular collapse (shock); after disease states associated with hypoxemia.

Warnings: Use during pregnancy is to be avoided.

Precautions: 1. *Starvation Ketosis:* This must be differentiated from "insulin lack" ketosis and is characterized by ketonuria which, in spite of relatively normal blood and urine sugar, may result from excessive phenformin therapy, excessive insulin reduction, or insufficient carbohydrate intake. Adjust insulin dosage, lower phenformin dosage, or supply carbohydrates to alleviate this state.

Do not give insulin without first checking blood and urine sugar. 2. *Lactic Acidosis:* This drug is not recommended in the presence of azotemia or in any clinical situation that predisposes to sustained hypotension that could lead to lactic acidosis. To differentiate lactic acidosis from ketoacidosis, periodic

determinations of ketones in the blood and urine should be made in diabetics previously stabilized on phenformin, or phenformin and insulin, who have become unstable. If electrolyte imbalance is suspected, periodic determinations should also be made of electrolytes, pH, and the lactate-pyruvate ratio. The drug should be withdrawn and insulin, when required, and other corrective measures instituted immediately upon the appearance of any metabolic acidosis.

3. *Hypoglycemia:* Although hypoglycemic reactions are rare when phenformin is used alone, every precaution should be observed during the dosage adjustment period particularly when insulin or a sulfonylurea has been given in combination with phenformin.

Adverse Reactions: Principally

gastrointestinal; unpleasant metallic taste, continuing to anorexia, nausea and, less frequently, vomiting and diarrhea. Reduce dosage at first sign of these symptoms. In case of vomiting, the drug should be immediately withdrawn. Although rare, urticaria has been reported, as have gastrointestinal symptoms such as anorexia, nausea and vomiting following excessive alcohol intake. (B) 98-146-103-D (6/72)

99% allergen-free air is here

If you wrote a prescription for 100% allergen-free air, we'd come within 1% of filling it. We're the ultra-clean air people. We're Dexon, Inc. — makers of Prime-Aire® Purifiers.*

Man's most efficient air filtering method

Heart of the Dexon Prime-Aire is a HEPA (High Efficiency Particulate Air) filter six inches thick. This is the absolute filter. The most efficient ever developed. It's structured from a dense, sophisticated glass fiber media developed originally for the Atomic Energy Commission to remove airborne radioactive contaminants.

Effectiveness

Prime-Aire's HEPA filter has an efficiency of 99 percent in removing particles 0.5 micron (one micron equals 1/25,000 of an inch) and larger. This includes bacteria, smoke, and fumes. It has even greater efficiency for larger particles, removing essentially 100% of such airborne allergens as dust, pollen, molds and yeast cells.

Operating mode

Prime-Aire's two-speed blower system draws in ambient air through the Dexon-designed pre-filter. This removes large airborne contaminants. Virtually all remaining airborne microorganisms are trapped in the HEPA filter's convoluted folds. Air flowing from the front of the unit is now in excess of 99% allergen-free. A controlled air velocity of 100 feet per minute assures quiet, draft-free operation.

Choice of Units

Two portable models are available. The illustrated Prime-Aire console model purifies the air in an average 1200 square foot home at least once an hour. This model is 18" x 18" x 22" high and weighs 35 lbs.

Our table model (not shown) filters the air in a 12' x 12' room five times an hour. It is 18" wide by 14" deep by 9" high, and weighs only 18 lbs. Both models are UL listed.

Easy care

The HEPA filter needs no washing. It's replaced about once a year if used continually. And less

often if used seasonally. The pre-filter is replaced monthly during continuous use.

Ordinary purifiers can't compare

Prime-Aire must not be confused with electrostatic devices. The Dexon HEPA filter never needs cleaning. Electrostatic filters require frequent removal and washing. Prime-Aire's filtering efficiency is rated at 99% and beyond. Average reported efficiency of electrostatic devices is 85%. Prime-Aire provides whisper-quiet operation. There's no arcing, snapping or ozone gas as generated by electrostatic methods.

Dexon's history of contamination control

Purifying air is nothing new to Dexon. Nor is it a sideline with us. We've been at it for nearly 12 years. Dexon ultra-clean air work stations are on the job in hospitals. Also pharmaceutical labs, food processing plants, microelectronic component firms and wherever contamination-free air zones are required. There's a reason: Dexon systems consistently meet or exceed Class 100 conditions of Federal Standard 209a for clean room and work station requirements.

Allergy sufferers breathe something rare

With Prime-Aire, many allergy patients have a proven weapon to fight — and often prevent — their suffering and discomfort. When breathing Dexon's ultra-clean air, many of these people report a degree of relief they never before thought possible.

An aid in many places

In promoting a healthful environment, Prime-Aire has uses that go beyond the home. It's also ideal for doctor's offices, consulting rooms, nursing homes — to name just a few places.

Medical data

To obtain documented performance data, write: Dr. I. A. Ismail, Director of Medical Products, Dexon, Inc., 3440 Belt Line Blvd., Minneapolis, Minn. 55416. Phone: (612) 927-5671

President's Letter

Change of Life?

TWO OF THIS issue's excellent articles highlight for me very important facets of our lives today . . . the observation by Wallinga that the physician must show to his children that they are as important to their parent as his patients, and Westman's postulate that in our culture remembering the past and planning for the future are rewarded but living for the present is frowned upon.

These two concepts provide a matrix upon which the shifting patterns of adolescence may fall into place. The constancy of change during the teens; the pairing of opposite moods, ideas, actions, roles is painfully familiar to parents of young people.

Since our family's sudden passage into non-adolescent status, several revealing observations have occurred to me. I have been struck with the realization that many of my adult patients, friends, as well as people unknown to me except by media reports, are acting much in the same fashion as adolescents. They are unsure of their worth and trying to find or prove it, at the same time disregarding the past and future while hedonistically living in the present. The exaggerated prolongation of the "youth culture," the exhibitionistic dress and sensual fulfillment promoted by advertising and various pseudo-psycho-social cults and reported sensationally by the media seems juvenile to the traditionalist.

Could it be that the changing life of the adolescent will continue until the "change of life" with no adulthood separating them? Hopefully no.

Continued searching for self coupled with present orientation is mandatory to prevent the stasis of cerebral lethargy and emotional barrenness. Perhaps if more teenagers can be adolescents, more of them will come to remember the past, plan for the future and be discerning enough to realize that we live now in the present. Perhaps they will allow their lives to change and thereby enrich ours.

George B. Martin

The Physician and His Adolescent

JACK V. WALLINGA, M.D.

ESSENTIAL IN dealing with any adolescent, particularly one's own, is to retain a sense of humor. Adolescence may be considered as the last of the common childhood diseases, from which most individuals recover spontaneously but occasionally it evolves into a chronic illness from which recovery is slow. Parents might best stand aside and let the teenager go through adolescence with a maximum of understanding and a minimum of advice. Anna Freud¹ observed that it seems easier, where adolescence is concerned, to describe the pathologic manifestations than the normal processes. She emphasized that adolescence, by its very nature, is an interruption of peaceful growth and a steady equilibrium of personality *is in itself abnormal* during this period. Once we accept the basic fact of adolescent disharmony within the psychic structure, understanding of teenagers and their problems is easier.

We need a rational basis for our behavior in dealing with adolescents, so we must strive for understanding of the adolescent process. Typically adolescents are often erratic, contradictory, egoistic and calculating, but at the same time, idealistic, generous, artistic and unselfish; perhaps more than they will ever be again. They fight their impulses, and they accept them. They love their parents, and they hate them; they revolt but still wish to be dependent. They thrive on the imitation of others while searching unceasingly for their own identity. It's not surprising that we are confused in trying to understand adolescents since they are so confused themselves. Some don't confide in their parents at all. This can be their normal self, but it is perturbing to the physician who is accustomed to people confiding in him and seeking his counsel.

Rebellion belongs to the freedom we have given our children by bringing them up in such a way that they exist in their own right.² By the time adolescence is reached, parents can only help a

little. The best they can do is to survive, to survive intact and without changing or relinquishing any of their own important principles. Parents may themselves grow along with their youngster's adolescent struggles. Ideally, the child enters adolescence at puberty in a state of uncertainty, facing difficulties and serious emotional conflicts, and then emerges from it, finally, with a stable socially acceptable adult pattern. The adolescent who does not experiment and who settles on a specific personality structure too quickly may not allow for the emergence, ultimately, of a healthy adult personality structure. During adolescence they may need to prove their dominance or their sexual identity, their independence, their virility, their potency and these proving tasks may become obscured by long hair, tight trousers, pierced ears, beards, mustaches and other bizarre manifestations of physical appearance and dress; all of this in the same youngsters who are almost paranoid at times about anyone looking at them or joking about their appearance. It's as if to be self-defeating and self-destructive is a test they must undergo. Adolescent manifestations take various patterns. We may see compensating coping patterns of compulsive studying or physical meticulousness or, at the other extreme, dropping out, copping out, drug abuse, running away, abandoning goals and standards or possibly attacking the world with a pseudo-sociopathic facade of indifference, insensitivity, and amoral, conscienceless protest. Underneath the veneer, however, may be very frightened, sensitive, anxious, guilt-ridden feelings which are not allowed to show. Some withdraw into abstract, philosophical, ideological states; others disassociate and may resemble schizophrenia, but they certainly should not be treated as schizophrenic. Adolescents can be very receptive to treatment. Psychotherapeutic support is preferable to isolation from the family, evicting them from the home, or confining them in a psychiatric ward which adds to the feelings of detachment, alienation and abandonment that are so overwhelmingly threatening to them.

Dr. Wallinga is Director of Child Psychiatry, Children's Health Center and Hospital, 2525 Chicago Avenue, Minneapolis.

Expressive

Adolescents are sometimes not verbal, but they are almost always expressive. Good communication with adolescents is primarily listening and closely observing with understanding. Lecturing, advising or criticizing either as a doctor or a parent, is rejected and quickly disrupts communication. Adolescents seek respect above everything else and, at times, respect for their desire for emotional distance and personal independence. Hair can be very effective to hide behind and for this the long hair styles are much more useful than short hair. The appearance of adolescent's rooms often reflects the chaos and confusion that they feel inwardly. Appropriateness of clothing as well as the feeling tone reflected are both important. The boy dressing in feminine colors may reveal his uncertainty about his masculine role; the rebellious, aggressive teenager proclaims his feelings with blaring reds and garish fashions while a withdrawn, hesitant youngster in bland beige or white expresses his uncertainty. Depression may show in black, drab, somber clothing. Overneatness and fussiness of clothes, hairstyle and bearing typify the adolescent who is handling his inner tensions through rigid compulsiveness and a lack of emotional flexibility. Baggy, formless clothes may deny and conceal sexual identity and maturity. Other teenagers announce their sexual urges to the world with clothes that are revealingly tight and exposing.³ The writings, the poetry, stories, diaries as well as pictures, choice of books, records and posters and youngster's reactions to music and lyrics are all revealing. Most adolescents are willing to talk, but only to those who are able and willing to listen to them. The physician-parent, as one who is listened to all day with deference and respect, cannot expect the same attitude from his own teenagers. His youngsters are quickly turned off by his expertise and experience which his patients gratefully pay to receive from him.

Depression

Depression is almost endemic for adolescents. Anna Freud observed that a strong fixation to the mother, dating from an early pre-Oedipal attachment to her, makes adolescence especially difficult to pass through. When the physician-father has been pre-occupied with his work and not sufficiently involved with the children, the dependency on the mother is intensified, hindering the youngster's ability to release anger directed toward the

parents and interfering with liberation from parental dependence. Adolescents need crises to differentiate themselves from their parents. Differentiation is more difficult when parents are psychologically sophisticated and are always agreeable and permissive with their adolescents, preventing crisis differentiation. Thus, some friction and some disagreement in a family is normal and very healthy, albeit disruptive.

Admitting to depression may be difficult for adolescents and a facade of clowning or pseudo-happiness is presented instead. Some youngsters stay up far into the night listening to records or the radio because they fear being alone or have insomnia. Restlessness, trouble concentrating, a decrease in school performance or obviously getting themselves expelled from school, dropping friends or previous activities or sports all may signal an underlying depression. Feelings of hopelessness, pessimism about the future, strong feelings of inadequacy, inferiority and a certainty of failure for their efforts are closer to the adult symptoms of depression. Irritability, boredom and lack of energy may lead to efforts to seek relief through drinking, drug abuse or sexual acting out. Some adolescents try all of these experiences in the search for relief and the pattern may spread to a broader delinquent behavioral spectrum. The sexual acting out, particularly, is an effort to gain closeness but, when guilt is created instead, there is further feeling of isolation and a vicious cycle is reinforced. Risks, and accident proneness are a more subtle aspect of the same dilemma. Some of the accidental deaths, particularly in automobiles, have a strong suicidal component. Suicide, one of the highest ranking causes of death in the 15 to 19 year age group, is reported increasing.

Drug Usage

Drug usage is particularly an area where understanding rather than angry, threatening lecturing is needed. Most adolescents try drugs experimentally and do not go on to heavy involvement or addiction. If youngsters are maintaining adequate academic, peer and recreational interests, more likely drug use is an aspect of healthy adolescent curiosity than in adolescents who are dropping out of their normal activities and compromising their emotional development by drug usage. Sometimes drug use wards off suicidal impulses and thus maybe temporarily even helpful. Parents

can better try to understand why children need to take drugs and then help them find healthier ways of meeting their needs than to become involved in undue surveillance, threatening or punishment. Physicians are, to the young people, the original "pushers" who prescribe pills (unnecessarily?) for relief of a multitude of subjective problems by chemical panaceas. The drugs that youngsters often first start abusing are their parent's, readily available in the medicine cabinet. Physicians need to be especially careful with drug samples in the home.

Physician-Parent

Physicians, with often compulsive strivings, perfectionistic personalities and great dedication and achievement, may seem high on pedestals, far out of reach and communication to their children. They tend to expect more of their children, or the youngsters expect more of themselves, because of

the standards set for them simply by the parent's life style. Parental affection for them and concern about them are often misinterpreted as only mistrust and lack of confidence in them.

The physician's success—academically, financially and socially—often is seen by his own adolescents as an insurmountable obstacle. Their basic insecurity and uncertainty does not allow them to imagine that they might reach the same heights or go even further. The physician's load of responsibility and the demands of his profession may not be goals to which his children can aspire. It is extremely important to separate and differentiate the doctor role from the father role, particularly when offering counsel to one's children.

The physician-parent is extremely busy with very important work—other people's lives. His adolescents need to clearly know that they are just as important.

Friedman-Roy Syndrome

This eponym is proposed for a hitherto unnamed group of central nervous system manifestations that include feeble-mindedness, motor symptoms, and reflex changes. The combination of findings described by Friedman and Roy as "an unusual familial syndrome" occurred in six siblings, whose parents were cousins and of average intelligence. An aunt was feeble-minded and had convulsions.

The chronologic age of the children ranged from seven to 17 years, but in no instance did the mental age exceed three years. Motor symptoms included speech defects and disturbances of extraocular movements including strabismus. Also present were extensor plantar reflexes and bony deformity of the feet (clubfoot). There was no evidence of progression, but no improvement occurred. The mother had internal strabismus and a positive Oppenheim reflex. Electroencephalograms of the mother and children revealed a striking similarity with uniform tendency toward high voltage and irregular frequency. Because of the reported absence of similar findings in antecedents, a classification with the usual heredofamilial syndromes is not possible.

Understanding Teenagers

JACK C. WESTMAN, M.D.

THE AMBIGUITY OF adolescence is well known. When a child becomes an adult concerns not only the youngster, but also the pediatrician and internist in defining the age boundaries of their practices, state legislatures in establishing eligibility for adult privileges, and parents in their continual review of the ability of their growing child to assume responsibility for himself. All of this is compounded by the fact that adolescence submits to generalization no more readily than any other age span in life. Each teenager is a unique individual with his own particular assets and liabilities.

A feature of the adolescent years is that a few months or a year can make a significant difference in the developmental level of an individual. We pay little attention to whether or not an adult patient is 30, 35 or 40. There is a great difference, however, between a 13-year-old and a 17-year-old, years of change and variability. This accelerated change, coupled with transition from childhood to adulthood, is responsible for common misunderstandings of youth.

Adolescents Are Growing Up to be Something

One of the illusions confronting youngsters, and shared by adults, is the belief that young people are growing up to be something. This view holds that childhood and adolescence are preparatory to something later in life. As a result simply being a four-year-old, ten-year-old, or 15-year-old is seen as an incomplete existence. Young people, according to this view, are working toward something that will come later. A resulting attitude is that if one works hard and waits, life will become better. Built into this attitude is also the notion that to live for the moment is psychopathic or, at least, immature. The implication is that normal people do not live for the present. Planning for the future and remembering the past are rewarded; but living in the present is frowned upon. As a result, life for many teenagers seems to have the

flavor, "If I can just get through these years, I'll find my real self and real living later."

Teenagers are driven by strong desires to live their present lives fully. This fact brings them into conflict with the belief that their lives are incomplete and that fulfillment should be deferred. A past-future cultural orientation is thrust upon adolescents, who can intellectually contemplate the past and the future, but whose strivings are oriented toward the moment.

Heightened Sensory and Sensual Sensitivity

The progressive maturation of the central nervous system through the teenage years is reflected in keenly felt sensitivity to perceptions, ideas, impulses and urges. This heightened awareness of the world and of themselves is expressed through teenagers' thoughtful, sensitive concern for themselves and others—at moments.

The exquisite insight of adolescence is illustrated by a 15-year-old girl who listened to a discussion of how youngsters become delinquent. During the discussion the point was made that delinquents often come from homes in which there was too little, or too much, love. The implication was that the parents of delinquents either neglected their children or put them on pedestals. The point was made that some mothers overindulge their sons, leading them to have little respect for the wishes of others. This 15-year-old girl challenged the point that delinquency could arise from too much love. She said, "I think that a mother who smothers her child with 'love' and puts the child on a pedestal really doesn't love him—only herself."

Together with heightened sensory and intellectual sensitivity, the body image in the parietal cortex also undergoes change and develops a more sophisticated representation of the body. As is known from the neurological study of rapid changes in body conformation, such as with the amputation of a limb, the body image requires time to adapt to change. With the rapid growth of the adolescent's body, discrepancies exist between the body image and the actual structure of

Dr. Westman is a Professor of Psychiatry, University of Wisconsin, Madison, Wisconsin.
See editorial, page 135.

he body. This adds a possible neurological component to the adolescent's psychological reaction to his rapid body growth. At times, his body "doesn't feel right." Some of the adolescent boy or girl's time in front of the mirror is related to narcissistic self-admiration, however, some is also related to the youngster's attempt to become acquainted with the "feel" of his changing body structure. A boy admiring his physique in front of the mirror is not only testing his power, but also new sensations. The girl combing her hair at length before a mirror is not only preening, but also becoming familiar with herself. The discrepancy between the actual body structure and body image contributes to the strangeness and the discovery of the adolescent years.

The primary and secondary sexual changes occurring as a result of augmented male and female sex hormones are well known, however, the gradual response of target organs and the reaction of the body to the increase in these powerful agents has been overlooked. This increase in glandular activity, in part, is responsible for mood swings, dizziness, embarrassing ease of blushing and other autonomic responses that result as the body adjusts not only to advancing central nervous system maturation but also to new levels of hormone activity.

All of these physical changes during the teenage years contribute to the adolescent's need to accommodate to an ever-changing picture of himself and the world.

Trends during the Adolescent Years

Although the onset and termination of puberty is determined by physical growth, adolescence itself begins with the onset of puberty but ends as defined by cultural and social considerations. This means that adolescence may be a brief period in a primitive society beginning with the onset of puberty and ending with the pubertal rite of circumcision at which point the individual becomes a member of adult society. At the other extreme, in urbanized societies the end of adolescence may be deferred until the third or fourth decade of life until adult responsibility are formally assumed. Increasingly in the United States, adolescence tends to fade away.

For the middle-class American, adolescence can be conveniently divided into three periods: early adolescence (ages 13 and 14), middle adolescence (ages 15 and 16), and late adolescence (17 and

18). There are significant differences during these years posing characteristic developmental issues.

The early adolescent is pre-occupied with accommodating to bodily changes and sensations. It is during this time that the youngster becomes aware of smells, views and sounds that held little interest during earlier years. Inhaling odors on the walk to school can lead a teenager to dawdle. The experience of sexual urges leading to affectionate feelings present the early adolescent boy and girl with hitherto unknown, embarrassing and exhilarating sensations. As an illustration, a 14-year-old boy may be largely preoccupied during a class in school with fighting off sexual arousal. His teacher may assume that he lacks interest in the class, being unaware of the more pressing matter—the boy's fear that when he stands up his erection will show. A 14-year-old girl may be distracted in school by the color of her teacher's eyes. Her teacher may be totally unaware of the reason for her apparent interest in social sciences. Learning to live with and cope with sensations and emotions is a vital part of all teenage years, but particularly during early adolescence.

"Trying on" Personalities

As fourteen blends into fifteen and then sixteen, the interests of youngsters move beyond their own bodies to exploring relationships with other people. At times boys and girls may be thrust prematurely into sexual encounters before they have had an opportunity to become fully familiar with their own bodies and explore feelings and ideas about themselves. A problem for today's adolescent is that his social environment tends to force him into sexual activity, depriving him of the opportunity to gradually become acquainted with himself and others. Many middle adolescents assume a pseudomature stance, acting like "swingers" in an effort to shed the trappings of childhood. Some of this is subtly encouraged by parents who promote dating and mating.

From the developmental point of view, the middle adolescent is attempting to discover both himself and others. Socializing for him is less a sexual activity and more a way of "trying on" personalities. Depending on one's socio-economic and cultural position, dating can assume many shapes and forms. Most boys date girls in the traditional sense, however, in many urban areas dating is being replaced by group activities and informal arrangements between the sexes. In

general girls feel increased freedom to take the initiative with boys.

In addition to the social pressures many teenagers feel toward early and active sexual relationships, the affects of over-population and urbanization are contributing to the decline in gradual exploration and experimentation with members of the opposite sex. Youngsters living in urban areas find themselves deprived of neighborhood and school-based peer support as is still available in smaller communities. The result is that the typical urban adolescent is more "at sea" in validating his identity with other teenagers upon whom he can depend. One of the most important aspects of role experimentation is having dependable feedback. With increasing changes in schools and neighborhoods and the large size of secondary schools, it is becoming more difficult for the adolescent to find reference groups who will "stick with him." On the positive side, the wider range of social contacts for the middle adolescent leads to greater comfort in strange situations and reduces inordinate dependency upon the familiar. In general, our middle adolescents find themselves more comfortable in new situations and are less inhibited in expressing their needs and carrying out plans for themselves. On the negative side, urbanization has deprived the adolescent of the needed support and familiar ties that can tide him over the vicissitudes of growing up.

Urbanization has also contributed to wider sexual experimentation in that many young people are reluctant to become involved sexually with acquaintances. These adolescents will have sexual relations, however, with strangers or people who are not known to their families. It is this seduction into early sexual activity based upon the relative lack of fear of repercussions that poses definite problems for the development of each adolescent. Ideally a teenager gradually first becomes familiar with his own body and its sexual capabilities and then transfers these sensations and feelings to other persons.

To the surprise of many adults who have forgotten their own adolescence, interaction between adolescent boys and girls is much more at the social than at the sexual level. Boys and girls use each other to find out what they are and how they would like to be. Their experimentation may include periods of minor antisocial behavior. They try on various roles: acting too old, young, "tough," debonair, or coarse. This role experi-

mentation resembles the peacock strutting and fanning his feathers and casually, but intently, observing the result. During this time a youngster may rise to the full height of oratory and produce resounding ideas, exercising to the fullest her newly attained intellectual skills. At a later moment, the girl, who is the lead in her class play, cannot attend practice because she has locked herself in her room at home. Families are acutely aware of the "crazy" behavior of the adolescent, a side ordinarily not displayed at school or in the neighborhood. A healthy respect for the role experimentation of the adolescent is in order. Being too frank with a teenager who is trying a role on for size does not take into account the developmental aspect of his behavior. If a teenager is clearly "playing a role" and is challenged by the question, "Is this really you?" she may bust into tears and vent her wrath. From her point-of-view, and in reality, experimenting with roles is her real self.

High School Senior—College Freshman

Late adolescence flowers during the senior year of high school and the succeeding year or two. If college is involved, decision making is deferred, however, the central issue is settling on one's identity. Although an exceedingly complex concept, simply stated, identity is everything subsumed by one's name. In other words, Bill Smith's identity is reflected in everything that comes to mind as one thinks of Bill Smith. Following experimentation with a number of ways of behaving and feeling, the late adolescent concentrates on "being me." Although associated with career choice, a solid sense of one's being permits a deeper level of relationship with others, leading to the capacity for commitment to goals and other people. The late adolescent depends upon feedback from others in order to give him a clear sense of his assets and liabilities.

For the successful adolescent in our society, the attainment of a well-defined identity and awareness of one's value of life grows. But for a young person who isn't successful in externally obvious and comparative ways, a sense of self-identity comes with difficulty. Young people are in the throes of painful recognition that a sizeable proportion of the population is frankly disadvantaged and that the majority lack the talents and gifts required for positions of leadership. In one school class there may be a few A, many B and C and a

few D students. The amorphous middle majority is awakening, however, and taking a more visible and powerful form. Labor unions have legitimized the identity and dignity of working men and women. Long weekends and vacation travel are no longer the domain of the wealthy. In fact, the largess of the rich is rapidly being absorbed by an affluent middle-class.

We are witnessing the rapid demise of a value that has been implicit in our social system, namely that people are rank ordered according to their wealth and their productivity. Although the clearly defined social classes of the past provided external knowledge of "one's place," that system prevented the individual from gaining a sense of importance and adequacy. What has it been like for Bill Smith, the C student, the fellow who can't play football well, the boy with little distinguishable talent, the boy who is just Bill Smith? Bill Smith's chances are better today. We are moving into the age of the "common man" in that differences between people are becoming less likely to be determinants of their human rights and opportunities—and their self-esteem.

To Err is Bad, but Getting Caught is Worse

The need to classify and evaluate people persistently arises for practical reasons. We are reaping, however, the long range impact of processing youngsters through an evaluation system that clearly defines the "good" student as distinct from the "poor" student. Our attitude towards learning has imparted to youngsters the idea that it is wrong or "bad" to make mistakes. We have led our children to assume that the expected and desired thing is to be correct, whether it be in knowledge or actions. In some instances children show what might be regarded as an "error-phobia." As a result some youngsters give up and become under-achievers. Why should they try? They will only end up with Cs. "If I can't be the best, why try?" Other youngsters resort to cheating, reasoning that it is better to conceal mistakes than to admit error.

A 13-year-old boy was asked to define stealing. He said, "Stealing is when you take something and get caught." When asked, "What do you call taking something without being caught?" the boy replied, "That's not stealing." The boy's attitude was clear—one is concerned first about appearances. If "bad" behavior shows to others, there is a problem. If not, there is no problem.

Communicating with Adolescents

In spite of their improved position today, adolescents still have difficulty being themselves and living their age fully. As previously indicated, our society does little to recognize the legitimacy of childhood and adolescence. Although drinking fountains are lowered and smaller desks provided, it is the unusual school system that successfully relates itself to the inner life of young people. Surprisingly, many teachers are unable to talk with young people. We frequently find today that teachers, nurses and physicians call upon the child psychiatrist to help them learn how to converse with the young. It is a stark fact that people who devote their professional lives to working with children are only now facing the simple question, "How can we find out what young people are thinking?" We are only beginning to see barriers break down and dialogue emerge between generations.

One of the pitfalls for adults in approaching younger people is the hope that it is possible to really completely understand adolescents and convert them to adult ways. The psychiatrist frequently encounters parents who say, "We want to get to know our 15-year-old girl; we feel we are losing her; and we want her to be free to say anything that she wishes to us." The parent who talks about establishing a close relationship with an adolescent is fighting the growth process. He runs counter to the burgeoning independence of the teenager. From birth onward, children grow away from adults at a rate that accelerates during the adolescent years. We often are inclined to overlook the necessary and useful distance between generations.

In the Adolescent's Shoes

One way to put ourselves in our teenager's shoes is to recall our own adolescent days. Those of us who are presently middle-aged didn't worry much about how our fathers felt about the Depression or World War II. We didn't worry much then about what our mother was doing to further community action. It is doubtful that we worried very much about whether our parents smoked or drank too much. On these points times have changed: these are real concerns for teenagers today. Advances in education and television have placed today's teenagers in a more sophisticated and socially aware position than was true in the past.

We may worry about our teenagers now, however, in many instances they are more worried about us. On the other hand, it is reassuring to recall that we did not show much direct gratitude toward our own parents when we were young. In fact we were much like present teenagers in lavishing criticism and withholding praise.

Many adults today feel with some justification that young people have too much freedom and not enough responsibility. This view may be tempered by the expectation that tomorrow they will join the stodgy middle class. The fact is that our present adult generation is a far cry from that of our parents. We did not become like them. In a similar way, our young people will not find their lives in our images. Social change has and will occur.

Adolescents Challenge Adults

The experience of the late sixties has taught us much about conflict that can arise between young people and older people. Cross-generation relations have often taken the form of battles. Many adults have become aware of the "threatening enemy" image of the teenager, a view which leads to instinctive recoil and suppression. On the other hand, there is a growing recognition that most adolescent protests are bids for recognition and challenges for adults to define their positions. Many teenagers despair because of the lack of sincerity and conviction of their parents, communities and teachers. As one girl put it, "When I push you, you give in like a marshmallow, or you crash down on me when it's unimportant. If I stay out late at night, you either overlook it or you ground me for a month."

A teenage delinquent boy referred to a psychiatrist because of auto-thefts illustrates how teenagers push us, hoping that we won't crumble.

After entering psychiatric treatment, the greatest evil in his life became his "lousy head-shrinker." During his appointments he complained that all that happened was talk. He insisted he did not need to see a psychiatrist because there was nothing wrong with him. One day he launched into a tirade, "I don't have to see you. I'm missing out on more important things. What do I have to talk to you about? I'm never coming back." At the end of the appointment time he repeated that he did not need help, but, as he was leaving, he asked without changing his expression, "When's my next appointment?" When told that the therapist would be gone for two weeks, he appeared crestfallen. When asked, "Do you think you can last that long?" he replied, "Well, I guess so." Suddenly the dependency and weakness that lay beneath his adolescent bravado were revealed.

Do We Really Want to Understand Teenagers?

Although it is clear that mature adults and the resources of society are devoted to the nurturance and welfare of our young, it is also true that we are both afraid of and threatened by young people. It is not pleasant for adults to be reminded of their weaknesses and to face the criticism of the young who see our faults so clearly. It is not pleasant for parents to witness the progressive growth of their children away from them. It is discouraging to accept the fact that our young people will no longer need adults, and one day may care for us. But of greatest importance is the obvious fact that one day the young will take the place of the older. It should be no surprise, then, that adults hold ambivalent feelings toward the young and that the potential for misunderstanding and mistrust abounds between generations.

A Biggen he had got about his braine,
For in his headpeace he felt a sore payne.
His hinder heele was wrapt in a clout,
For with great cold he had gotte the gout.*

*Edmund Spenser, "The Shepheardes Calender" (May), 1579.

Practical Aspects of Adolescent Growth and Development

W. A. DANIEL, JR., M.D.

ADOLESCENCE IS A PHENOMENON rather than a biologic period. Puberty is that part of adolescence associated with rapid growth and development and characterized by the ability to beget or bear children. It is unknown just what occurs in the body to start the secretion of specific hormones bringing about pubertal changes, but we do know that the time of onset occurs at different ages for different individuals with each child having a specific velocity of change but all progressing in the same sequential pattern. There are objective milestones of physical maturation that the physician can use in following the growth and development of adolescent patients and these important stages are related to many conditions seen in office or hospital practice. A five-stage scale of evaluation has been developed by Tanner¹ and is used by most physicians caring for large numbers of adolescents. These characteristics are listed in Tables

1 and 2.

The above concept is based upon the relationship of body changes to the stages of maturity, not necessarily to age. This means that many developmental alterations occur at specific maturational stages and not at particular chronological periods. In our clinic the mean hematocrit for a boy of any age at Stage 4 is 42.25, and is 39.6 for Stage 2 at any age. In practical terms a 12-year-old boy with almost adult development should have more hemoglobin than a 15-year-old boy who has just begun pubertal change. The relationship carries over into management of, for example, diabetes. The boy or girl who has reached Stage 4, regardless of age, will probably need less calories than one at the peak of the growth spurt. If the physician records the maturity stage of his patient at each office visit he has a record of the pattern of growth of the individual boy or girl and may recognize abnormalities of development earlier than age-based changes.

The growth spurt usually occurs between 13

Dr. Daniel is a Professor of Pediatrics, and Director, Adolescent Unit, University of Alabama Medical Center, 1919 Seventh Avenue, South, Birmingham, Alabama 35233.

TABLE 1
Classification of Genitalia Maturity Stages in Boys

Stage	Pubic Hair	Penis	Testes
1	None	Preadolescent	
2	Slight, long, lightly pigmented	Slight enlargement	Enlarged testes; scrotum pink, texture altered
3	Darker, starts to curl, small amount	Penis longer	Larger
4	Resembles adult type, but less in quantity, coarse, curly	Larger, glans and breadth increase in size	Larger, scrotum dark
5	Adult distribution spread to medial surface of thighs	Adult	Adult

TABLE 2
Classification of Sex Maturity Stages in Girls

Stage	Pubic Hair	Breasts
1	Preadolescent	Preadolescent
2	Sparse, lightly pigmented, straight, medial border of labia	Breast and papilla elevated as small mound; areolar diameter increased
3	Darker, beginning to curl, increased amount	Breast and areola enlarged, no contour separation
4	Coarse, curly, abundant but amount less than in adult	Areola and papilla form secondary mound
5	Adult feminine triangle, spread medial surface of thighs	Mature; nipple projects, areola part of general breast contour

and 15½ years of age in boys and during this time they have an increase in height of about eight inches. In the year of peak growth velocity about four inches in height are observed. The boy usually adds about 40 pounds of weight during the period of rapid growth. Girls begin their growth spurt earlier, about age 12 years, and complete it by 13½ years.

Following these peaks height continues to increase but at a greatly decelerated rate. The pattern of growth finds that legs lengthen first, then thigh breadth occurs and this is followed by an increase in shoulder breadth and finally trunk length. Increased height is due chiefly to lengthening of the trunk and legs. Muscle size also increases. Pre-pubertal boys and girls show little difference in muscular strength but with puberty, the boys' muscles increase in size and strength, particularly the muscles of the shoulder girdle and back. All of these changes are correlated with maturity stages and may be easily followed by the physician.

Puberty is characterized not only by physical change but is associated with mental and emotional development of the individual. A simple checklist for mental-emotional growth should be part of each office visit. The adolescent must free himself from his family in that eventually he must become responsible for himself and his welfare; he must develop an appropriate, acceptable sexuality, there must occur an awareness of the need of a vocation and plans for training and he must develop an ego identity by which he knows who

he is, where he fits into societal and peer relationships and how well he accepts himself. These are maturational milestones and should be part of the health evaluation for adolescent patients. And just as there are stages of physical development, so must one expect the 13-year-old patient to have a lesser degree of personal responsibility than the 17-year-old; the young adolescent would have different ideas concerning a future vocation than the older adolescent; but, both should be making progress in these and the other areas that have been listed.

Many difficulties of modern adolescence are due to the fact that various physical, mental and emotional objectives or goals towards which these teenagers are expected to strive cannot be reached at the same time. It would be extremely rare that physical maturity, responsibility for oneself, intellectual balance and emotional stability were accomplished at the same time. As a result of these different schedules and rates of growth and development there are still many needs of the child and the desires of the adult in every adolescent. Much of the apparently irrational behavior and unrealistic expectations of adolescents can be prevented or eradicated by help from understanding adults, particularly interested physicians.

Use of the sex maturity classification and the checklist of mental-emotional development provides a rational means of following the development of adolescent patients and particularly should be employed with any serious illness or handicap which, in itself, may alter physical or emotional growth.

Pregnancy: An Adolescent Crisis

FRED E. MECKLENBURG, M.D.

ADOLESCENT PREGNANCY has been defined in various ways. Pregnancy with delivery occurring to mothers less than 16 years of age is considered an "adolescent pregnancy" in the studies herein cited. It is not within the scope of this article to review all the literature. A number of studies to evaluate trends which will give a public health and societal perspective of the problem will be reviewed. Current thinking regarding the medical hazards of adolescent pregnancy and personal implications from the standpoint of the patient herself will be presented.

From the societal point of view, numerous studies have demonstrated the scope of the problem. Dempsey and associates¹ studied adolescent pregnancy in the city of Baltimore. They found from 1959 to 1961 that mothers less than 16 years of age contributed 1,000 live births annually. At that time the likelihood that a girl enrolled in the Baltimore school system would have a pregnancy during the fifteenth year of her life was 3.7 percent. This means that one out of every 30 girls in the Baltimore school system gave birth to a child during her fifteenth year of life. This included 3.3 percent of the girls who had never been pregnant before. Girls who had delivered a child previous to their fifteenth year of life had a likelihood of 27 percent that they would deliver a second child during their fifteenth year.

Studies from Great Britain^{2,3} have shown that trends in adolescent pregnancy parallel those in the United States. Between 1956 and 1966 the number of pregnant girls in Great Britain between the ages of 13 and 15 rose from 269 per year to 1,288 per year. Eliminating the factor of the increasing number of girls in this age group, there still is a very significant difference, with birth rates in this age group rising from .8 per 1,000 girls to 3.2 per 1,000. This is a fourfold increase over that ten-year span.

Data from the state of Minnesota⁴ show a similar increase in the number of very young mothers,

although of lesser magnitude than the studies cited above. Our vital statistics place all women giving birth under the age of 17 in the adolescent group. In 1950 there were approximately 61,000 girls in the age range between 15 and 17 in our state. There were 215 babies born to this group. Twenty years later the number of girls in that age group had practically doubled to 113,000. (This represents the peak of the post-World War II baby boom.) The number of babies born to this group has quadrupled, from 215 to over 1,000 babies in 1970. Adolescent pregnancy is a very real problem in Minnesota.

The Table demonstrates the data from the state of Minnesota over the past five years. The number of juvenile mothers under the age of 15 has been surprisingly constant. Girls between the ages of 15 and 19 contribute approximately 20 percent of the illegitimate births in this state.

In Minnesota in 1971 almost 60 percent of the babies born out of wedlock were born to mothers under the age of 21. Twenty-one percent were born to mothers under the age of 18. Total teenage pregnancies (the majority of which were conceived out of wedlock whether or not marriage followed) accounted for 11 percent of total births in 1971.

TABLE
Minnesota Live Births
By Year and Age of Mother

Year	Total	Under 15	15-19
1967	64,532	40	7,129
1968	64,759	46	7,456
1969	65,961	43	7,491
1970	68,449	44	8,102
1971		40 (fiscal year)	illegitimate only

Almost 60 percent of all babies born out of wedlock last year were born to mothers under 21 years of age.

Almost 21 percent of all babies born out of wedlock last year were born to mothers under 18 years of age.

Total teenage pregnancies account for 11 percent of live births. Adolescent pregnancy (less than 15 years of age) accounts for less than 0.1 percent in Minnesota.

Why should so many babies be born to these child-mothers? Cutwright,⁵ a sociologist from Indiana discusses several reasons. He minimizes the effect of changing sexual behavior. He states that the major change is the decrease in the age at which girls are physiologically able to reproduce.

Dr. Mecklenburg is from the Department of Obstetrics and Gynecology, St. Louis Park Medical Center and is Clinical Assistant Professor, Obstetrics and Gynecology University of Minnesota.

See editorial, page 135.

Over the past 20 years, this age has decreased by approximately one year, shifting the whole scale of reproduction down one year. This mathematical manipulation can account for the majority of adolescent births. Add to this the reduction of pregnancy wastage which has been brought about by improving nutrition and improving maternal care. Many babies that otherwise might have been still-born or spontaneously aborted by these very young mothers 20 years ago can now be carried to term because of improved prenatal care. Cutwright concludes that increased sexual activity plays a minor role.

Traditional medical attitudes about adolescent pregnancy have been drawn from studies that included primarily the very lowest socio-economic group receiving the very worst possible medical care. The statistics were frightening. The classical view has been that the girl who was less than 15 years of age and pregnant had a seriously increased risk of toxemia, an increased risk of severe anemia, an increased risk of prolonged labor, more premature births, higher perinatal loss, greater risk of prenatal and postnatal infections and higher percentage of operative deliveries including both forceps and cesarean sections.

Recent studies, however, have demonstrated that socio-economic factors played a greater role in creating these pregnancy problems than did the age factor. It has been demonstrated repeatedly that with adequate prenatal care the complication rates drop drastically.

Zackler,⁶ reporting the experience of the prenatal clinic sponsored by the Chicago Board of Health, included a group of 2,400 patients 15 years of age and under. He demonstrated that prematurity rates could be cut by one-third by simply providing adequate prenatal care. The perinatal death rate was cut in half in the group of patients receiving adequate prenatal care. The toxemia rate was cut in half. There was a major reduction of all complications to the point that complication rates in the population of girls age 15 and under were not significantly higher than might have been expected for a similar population ten years older.

Sarell⁷ reported on the experience from Yale University where a special program called the "Young Mothers Medical Program" has been instituted. His program includes a combination of excellent medical care with continuing education. Although the study was small with only 119 patients 15 years of age or younger, his reported

complication rates were surprisingly low. He demonstrated that these patients had shorter than expected duration of labor. There were no cesarean sections in the study group.

A large study reported from Syracuse, New York,⁸ demonstrated similar findings. Particularly noteworthy were the very low complication rates.

Physicians must be concerned when providing prenatal care for a very young mother. With adequate medical care, pregnancies in this group should be no more medically intolerable than in any other age group.

The major crisis in adolescent pregnancy is the personal experience of the pregnant girl. A major emphasis must be made on attempting to predict which girls are most vulnerable to pregnancy at this early age. Is it possible to anticipate the adolescent mother? The study from Syracuse suggests this is possible. Several factors show up repeatedly in their population of very young mothers which should alert school authorities, family physicians, or social agencies to a "high-risk" adolescent girl.

The marital status of the child's parents is one such factor. In the Syracuse study, only 41% of their adolescent mothers came from families where the parents were living together. Forty-six percent were divorced or separated. In 12% of the cases, one or both parents were dead. One-parent families seem to predispose to adolescent pregnancy. A second factor which showed up with surprising frequency was chronic truancy. More than 50% of the girls had an early history of repeated unexplained absences from school, often starting at age 10 or younger. An alert school administration should be able to steer the chronically truant child to individuals or agencies which might help her to avoid the crisis of adolescent pregnancy.

The sexual history of adolescent mothers demonstrated that 73% of these girls had been sexually active for two years or longer prior to their pregnancy. Available contraceptive services and programs of adequate family life and sex education should allow us to reach these sexually active girls long before they end up in the physician's office seeking either prenatal care or abortion.

Adolescent pregnancy may represent rebellion or an attempt to punish the parent or parents for an unhappy home situation. This degree of rebelliousness should not be difficult to detect in the adolescent population. The rebellious child representing a definite high risk for early pregnancy deserves particular help in dealing with her multi-

faceted problems.

A study presented in the British Medical Journal⁹ dealt with suicide risks. The risks of suicide committed during a pregnancy is extremely low. This is true whether the pregnant woman is adolescent or otherwise. The study from England showed that in a group of women who had been pregnant prior to 18 years of age, the risk of subsequent suicidal behavior was much higher than expected. This high risk was related to several factors. Suicide was much more likely if the patient remained unmarried. It was also more likely if she came from a higher socio-economic group, if she were Roman Catholic, or if she had a subsequent history of venereal disease. There is *no* evidence to suggest any difference in the suicide risk if the patient carried to term or was aborted. The authors conclude that the pregnancy and the subsequent suicidal behavior are two symptoms of the same disease, and not cause and effect. The young girl with an underlying adolescent psychiatric problem is more vulnerable to adolescent pregnancy and is subsequently more vulnerable to suicidal behavior. We are dealing with a disturbed child who will frequently grow up to be a disturbed adult. Both the sexual and the suicidal behavior are evidence of an underlying adolescent disturbance.

Recidivism rates among adolescent mothers are high. Sarell and Davis,¹⁰ in their 1966 Baltimore study, demonstrated that over 90% of the adolescent mothers subsequently had one or more additional out-of-wedlock pregnancies in the next five years. Dempsey, in the study mentioned previously, demonstrated a 27% recidivism rate during the fifteenth year among patients who had one pregnancy prior to age 15.

Recidivism among the out-of-wedlock pregnant population is a problem also in Minnesota. Five percent of out-of-wedlock mothers less than 20 years of age have had one or more previous illegitimate children.

Several authors have described an unwed mother syndrome or unwed mother cycle. This starts with an out-of-wedlock pregnancy. The mother then drops out of school. She subsequently becomes a welfare recipient, followed by repeat pregnancies with loss of self-esteem and failure to become a productive individual. This cycle has been seen to be repeated again and again. It can be broken. It appears that the key point in breaking the unwed-mother cycle is continuing in school.

A program of multidisciplinary help is very important. These girls need adequate medical care, social help delivered in a non-judgmental, sympathetic, and loving manner, and continuing education. In Minnesota social workers are aware of the importance of this approach. Several excellent programs of continuing education are available for adolescent mothers. More than half of the pregnant high school girls continuing with their education in St. Paul are electing to stay in their own school rooms and continuing on until they are close to term. Alternative programs include "special schools" for pregnant women, of which there are several in the Twin Cities area, or home-bound teaching programs.

Undoubtedly, the best approach to the adolescent pregnancy is prevention. Prevention involves sex education and contraception.

The Figure demonstrates that the number of illegitimate births to women over the age of 21 in Minnesota has been declining whereas the contribution of women under the age of 21 is increasingly significant. This points out that progress has been made in reaching the older unmarried mother with sex education and contraceptive services.

Comment: The unmarried mother over 20 years of age (often a repeater) is declining.

Figure—Unmarried mother's age, seven year trend.

Few studies are available which show the positive results of sex education programs. A long-term study done by James D. Lockett,¹¹ instructor in marriage and family living at the Keokuk, Iowa, Senior High School, does demonstrate a very positive yield. His course is elective in the Keokuk High School and includes areas such as premarital sex, reproduction, venereal disease, family planning and the moral code. These are discussed from biological, emotional, and physical standpoints. The course may be elected by any high school student for either a semester or a year. The socio-economic level of the majority of the students taking the course is average or below. Over a 20-year period between 1947 and 1967, 60 percent of the girls in the high school were enrolled in the sex education course. This group contributed only 8.4 percent of the illegitimate children born in Keokuk. The 40 percent of girls who had not taken the course contributed 91.6 percent of the illegitimate pregnancies.

A parallel study on divorce including graduating males between the years 1947 and 1971 demonstrated an equally positive yield. The divorce rate among 1,664 males who took the course was 10.4 percent. The divorce rate among 554 males who did not take the course was 39.6 percent.

Sex and family life education *does* work and *is* important.

The contraceptive program established by Beasley¹² in the state of Louisiana demonstrates the positive results obtained by making contraceptive services readily available to anyone who needs them regardless of age or marital condition. In his pilot study in Lincoln Parish, he demonstrated a drop in the birth rate of 32% in the first year. This was at a time when the birth rate in four adjacent parishes dropped by 6%. In the Lincoln

parish the illegitimacy rate dropped 40% in the first year. The incidence of a second illegitimate pregnancy dropped by 41% in the first year.

A study published by the Office of Economic Opportunities¹³ in 1968 demonstrated a nearly total lack of contraceptive services for Minnesota's medically indigent population. They estimated that 70,000 or 88% of medically indigent women in Minnesota, were not served by family planning services. At that time there were only three counties that offered any significant family planning services for the medically indigent. The situation has improved since then with several county clinics having been organized. Planned Parenthood of Minnesota has opened three regional offices in Mankato, Rochester, and Bemidji. Through these programs they have been able to expand their services to another 22 counties. Between September of 1971 and March of 1972, they were able to reach 2,200 patients. This represents less than 100 patients per county, hardly the kind of saturation family planning services which are needed.

The Minnesota Obstetric-Gynecological Society two years ago unanimously approved a resolution supporting programs of responsible contraception which include: (1) support of Federal, state and local programs to provide contraception to all persons desiring such services regardless of age or marital status, (2) encouragement of individual physicians to provide such services regardless of the age or marital status of their patients . . . , and (3) encouragement of local school officials to institute programs of responsible value-oriented sex education in school curriculums at all grade levels.

The State Medical Association meeting in Duluth in 1970 considered and accepted a similar resolution. However, implementation of the program in these two areas has been slow.

The Adolescent with Venereal Disease

CHARLES S. MAHAN, M.D.

"IT'S NO WORSE than having a cold." This kind of statement is being heard with increasing frequency by health professionals involved in treating and counselling the patient under age 19 with gonorrhea. It is one of many reasons why the 10 to 19 year old age is becoming an increasing reservoir of both syphilis and gonorrhea.

National and Local Problems

For the past three years gonorrhea has been exceeded in numbers only by the common cold as the most common communicable disease in the United States. Syphilis has held third or fourth position over those years, but has not become epidemic, that is, out of control. The age group of 15 to 25 accounts for the highest number of gonorrhea infections nationally and locally, and the average age of the gonorrhea patient gets younger each year (Table 1).

TABLE 1
Percent of Gonorrhea Cases in
Younger Age Groups
Minneapolis, Minnesota

	Age 0-15	Age 15-19
1966	0.4	16.4
1967	0.9	18.5
1968	1.1	18.5
1969	0.6	20.2
1970	0.9	24.4
1971	1.1	24.0

In 1971, in the state of Minnesota, there were 1,520 reported cases of gonorrhea in people of ages 10 to 19.¹ Since surveys show that only 15% of venereal disease (V.D.) cases are reported, this makes an estimated 10,600 new cases of gonorrhea in Minnesota teenagers. There were 60,000 estimated new cases of gonorrhea in all age groups in Minnesota last year.

In Minneapolis, the Teen Age Medical Service

saw 1,880 people under age 19 for V.D. last year and treated 428 of them for it. This number has increased greatly in 1972. The Youth Emergency Service which has been a tremendous help in directing adolescents to health care, reports a significant shift in calls from drug abuse to V.D. and sex-related problems. The Red Door, a new venereal disease clinic in Minneapolis sponsored by city, county, and state, sees 1,000 patients a month, and 15% of those are under age 19. Twenty-two percent of these patients had positive tests for gonorrhea.

Why Is There an Epidemic of Gonorrhea in Adolescents?

Many reasons are given by V.D. experts as they grope for ways to check the runaway epidemic. Ignorance and fear breed a secrecy in adolescents which causes many not to seek treatment or to give up at the first rebuff. Venereal disease education is poor or nonexistent in the majority of Minnesota secondary schools and in a majority of homes. Couple this with a rapidly increasing number of young adolescents indulging in premarital intercourse, and an increase in sex-related problems (unwanted pregnancy, V.D.) has to result.²

The adolescent homosexual male with a large number of contacts is an increasing reservoir of new syphilis cases, as well as gonorrhea.³ A mistrust of the medical establishment (based on their past personal experiences) keeps many "gay" men from adequate treatment and follow-up.

The fact that 89-90% of women have no symptoms with acute gonorrhea creates obvious problems of epidemiology and treatment.⁴ Since an estimated 10% of all women with acute gonorrhea will develop gonococcal salpingitis if untreated and since an estimated 6-10% of salpingitis cases result in sterility, the asymptomatic woman is a great current concern.

Dr. Mahan is Assistant Professor, Department of Obstetrics and Gynecology, Hennepin County General Hospital, University of Minnesota Medical School, Pilot City Health Center.
See editorial, page 136.

Solutions to the Problem

There will be no easy solutions since no disease was ever treated out of existence, and a vaccine for gonorrhea appears to be many years away. We can expect the current gonorrhea epidemic to last five or ten more years before abating. There are steps we can take in the meantime to ameliorate the effects of the epidemic:

Better Use of Current Diagnostic Materials

All physicians and nurses who see adolescents for any reason should consider the possible presence of V.D. in that patient and ask pertinent questions regarding heterosexual and homosexual sexual exposure and practices.

In men, a Gram-stained smear of urethral discharge or rectal, throat, or urethral cultures on Thayer-Martin plates or Trans-Grow medium are the proper diagnostic steps for gonorrhea.⁵ A serology should be drawn for syphilis.

In women, Gram-stained smears are *worthless*, and Thayer-Martin or Trans-Grow cultures from cervix, rectum, and throat should be done as indicated. Some women will have positive rectal cultures and negative cervical cultures. This is due to either spread from vagina to rectum or direct exposure from rectal intercourse. Gonococcal pharyngitis is being found with increasing frequency at the Red Door in women and men with oral-genital sexual exposure. Again, serologies are important as syphilis and gonorrhea frequently travel together.

Adequate Treatment

Table 2 condenses the 1972 recommendations for gonorrhea treatment by the Public Health Service. Copies of this and of syphilis treatment schedules can be obtained from the Minnesota State Health Department.

Penicillin is still an excellent drug for curing gonorrhea in Minnesota. It is cheap, and by using the proper dosage in treating gonorrhea, one can be virtually assured of eliminating incubating syphilis at the same time.⁶

Generic tetracycline is used in patients with penicillin allergy. Doxycycline and minocycline have the same cure rate as generic tetracycline and require smaller dosage, but cost much more. Single stat doses of these drugs are no longer recommended for gonorrhea due to a lower cure rate.

Spectinomycin is a good new drug for gonorrhea, but has the same cure rate as penicillin and

TABLE 2

Gonorrhea Treatment Recommendations U.S. Public Health Service March, 1972

1. Preferred drug for treatment of uncomplicated gonorrhea at all sites is *penicillin*.
—DOSAGE: Aqueous procaine penicillin G, 4.8 million units I-M at 1 visit. (Men and women)
Give Probenecid (oral) 1 gm. at least 30 min. before injection.
Contacts—Patients with history of exposure to gonorrhea should receive same treatment as those proven to have it.
2. If penicillin contraindicated or ineffective:
—DOSAGE: Tetracycline HCl, 1.5 gms. initially, followed by 0.5 gm. four times a day for 4 days. (Total dosage 9 gms.) (Men and women)
3. Alternative to tetracycline or if tetracycline fails:
—Spectinomycin, 4 gms. I-M—men.
—Spectinomycin, 4 gms. I-M—women.
4. Follow-up repeat cultures seven to 14 days after completion of treatment.

tetracycline and a very high price tag. It is used as a back-up if the others fail to cure.

Gonococcal salpingitis and arthritis cases are being seen in much higher numbers now, and only early excellent care, including hospitalization at bed rest and high doses of I-V antibiotics, will prevent the serious crippling sequelae of these complications.

Prevention

Someone at home, at school, or in church, has to teach "responsible sex" during puberty to help adolescents handle the pressing sexual decisions they are increasingly having to make. This would prepare them for decision-making processes involving pregnancy prevention and V.D. prevention.

Using condoms, foam, or diaphragms would certainly help reduce the rate of gonorrhea in adolescents who elect to have sexual intercourse.⁷ Unfortunately these products are seldom used and are, incidentally, sometimes hard for the adolescent to acquire in Minnesota.

The intrauterine devices and oral contraceptives offer no protection against gonorrhea or syphilis, but in our experience, the person responsible enough to use them also seems to be responsible enough to avoid sexual partners with infections (Table 3).

Douching and washing after intercourse are of unknown value. Careful selection and maintenance of one's trustworthy sexual partner is probably the single most important preventive factor for those

who choose to indulge.

Increased public education efforts help warn adolescents of the epidemic nature of the diseases, signs and symptoms, and ideas for prevention and treatment.

TABLE 3
Clinic Variation in Positive
Gonorrhea Cultures. Percentage
Positive of Women Cultured.
Hennepin County General Hospital, 1971

V. D. Clinic	22 %
New Obstetric Clinic	4.5%
Family Planning Clinic	1.2%
All Women Cultured	12.5%

Easier Access to Care

Not enough can be said for the positive effects of the passage in 1971 of a law for treatment of minors in Minnesota. This has helped public and private health care agencies, and providers give care to the adolescent in a much more acceptable way. This results in fewer clashes with the establishment and more adolescent patients coming for help at earlier times. The individual knows he can be checked and treated for venereal disease in complete confidence if he so desires.

The generosity of practicing physicians in volunteering their time to "free clinics" and Teen Age Medical Service (TAMS) has also helped find the adolescent "back-log" of V.D. and bridge a wide confidence gap between adolescent and physician.

Counseling

An adolescent who gets gonorrhea often has many other problems. The Red Door and TAMS were purposefully not set up as World War II "Clap Shacks." They employ nurses, corpsmen, psychologists, and social workers as teachers and counsellors, as well as offering "the shots." While still early in the game, patient acceptance of counselling and teaching is usually enthusiastic, and it seems that this approach is reducing the numbers of "repeaters"—the adolescent who returns for treatment six or eight times a year with new gonorrhea infections. Clinics using this approach detect a hostile attitude on the part of the adolescent toward his educational institutions for not providing such information in the first place.

Conclusions

Most physicians and health professionals will treat gonorrhea, perhaps syphilis, and certainly adolescents sometime in the next year. The health provider must keep up to date with the ever-changing mechanics of treatment of the venereal diseases. He should also be willing to spend some time with the adolescent in sexual counselling and teaching. Good practices and serious handling of these nuisance sexual diseases today in the maturing young adult will help prevent the psychoses, paralysis, blindness, crippling, and sterility of tomorrow.

Drugs and the Adolescent

Current Trends

DOROTHY M. BERNSTEIN, M.D.

THE DRUG SCENE is changing. According to a recent survey of 6,943 college students, drugs are being outranked in interest and concern by: (1) Ecology, (2) Sex, (3) Pollution, and (4) Population problems.¹ Elsewhere there are indications of a decrease in epidemic drug use among the young. Telephone emergency services which developed to serve drug problems now report that only 10% of their calls relate to drugs.

However, those who are treating drug problems would not view the current situation as quiescent. As with any epidemic, there remain the susceptible cases and the unexposed cases in the form of the very young who are newcomers on the drug scene.

Sources of the Drug Scene

The present epidemic of widespread use of illicit and exotic drugs in the United States began approximately in 1963, according to Blum.² This centered around graduate students in university settings. In 1966, adolescents came on the scene as the "flower children" who began to use the psychotropic drugs. This group was replaced by alienated school dropouts with a rapid spread to the use of other drugs—methamphetamine, cocaine, barbiturates. Drug use at this point became epidemic with spread to other age groups. Unique to this epidemic as compared to other epidemics in history was the concentration of the epidemic in a young population—the teenage population, including a spread to grade school children. Previous epidemics have been among young adults and even more mature segments of the population.

The Current Picture

To assess trends in current drug prevalence in the community, a recent study of the population coming to the Mt. Sinai Drug Treatment Center

was examined. This included 250 outpatients seen over a period of 16 months. Of that number, 100 currently are on a Methadone Maintenance Program and 59 are in the Park Avenue Rehabilitation Center Program (PARC)—a group with nonnarcotic drug problems. Figure 1 shows the age distribution of the latter group. Of these 63% are adolescents ranging in age from 12 to 19 years. This population was examined in the following areas: (1) Age grouping and concentration, (2) Sex distribution, (3) Residence, (4) Drug of choice, (5) Source of drugs, (6) Duration of use and (7) Motivation for use.

Of the adolescent population, 22% are in junior high school and 78% are in senior high school. Peak use is in the 17 to 19 year old group. This compares in distribution with a recent survey of an entire school population of 56,000 junior and senior high school students by Gossett, et al.³ Their findings showed that 28% of the students had used illicit drugs only a few times; 8% had used drugs more than ten times; 4% used drugs frequently. The last group can be considered to be drug abusers. From various sources such as school surveys,⁴ referral centers, the counts, police services, and street drug counselors, drug

Figure 1

Dr. Bernstein is Medical Director of PARC, Mt. Sinai Drug Treatment Center, Minneapolis, Minnesota and Clinical Assistant Professor of Child and Adolescent Psychiatry, University of Minnesota Medical School.

See editorial, page 133.

abusers range from 4 to 5% of the school age population in the local community.

In sex distribution, 56% are male and 44% are female. This alters earlier figures in which drug users were predominantly male. At times the girls use drugs in mixed groups. At other times the groups are comprised of girls only. An example is epidemic abuse of Darvon or barbiturates reported in girls' schools. As to frequency of usage of any single drug, however, boys exceed girls in all categories.

In this study, 47% of users came from inner-city residences, whereas 53% are from the suburbs. Again, this reverses earlier figures in which the stronghold of drugs was in the inner city. Since this clinic serves a model city area, the figures for the suburbs are underestimated.

Figure 2 shows the distribution of individual drugs used by adolescents. Among the younger teenagers, poly drug use is the commonest phenomenon. Late teenagers show a single drug preference with amphetamines and barbiturates ranking highest. This constitutes a more serious problem because it represents the discovery of a single drug to meet a specific intrapsychic need. The young experiment with many different drugs and combine drugs, exposing themselves to overdose, potentiation of drug action, and side effects. They may inject into a vein a drug meant for oral ingestion. Many illicit drugs contain impurities that may be toxic or alter drug action. Still seen in young adolescent groups are epidemics of inhalant use, as for example, glue sniffing in Indian grade schoolers. In this clinic, only 1.5% of late teenagers were addicted to heroin. They were placed on a detoxification program initially

since the lower limit of the Methadone Maintenance Program is 21 years.

For young teenagers, the most frequent source of first drug experience is from drugs obtained within the home. To sustain drug use, supplies are easily obtained from peers or street sources. Amphetamines or heroin are obtained primarily from adult "pushers." At this Center, it has been found that teenagers usually are defensive about telling the source of their drugs. However, as a rule, they enumerate the drugs they are using freely and may even magnify the number.

Duration of use presents a varied picture. Younger drug users tend to be transient users. Older adolescents with a sufficient problem to be detected and referred to a drug treatment center have a longer history of consistent and repetitive drug use. They report starting with a wide variety of drugs at an earlier age. At this point, their life style often is beginning to show a chronic dependency on drugs. This is consistent with the findings of Shearn, et al.⁵ Their data suggested that the use of any drug before age 15 in psychologically vulnerable individuals points to future serious drug usage. This is particularly true for use of barbiturates and narcotics.

Why Drug Use?

No single pattern of motivation for drug use was seen. Three factors were found more frequently than others: (1) In younger, susceptible adolescents, drugs were found to be a means of gaining acceptance into peer groups. For many adolescent groups, drugs have come to be a form of initiation rite. (2) In younger, vulnerable groups, drug usage was found to be an exaggeration of the normal exploratory or curiosity urge as described by Harlow.⁶ (3) In the older group, drugs were used to cope with adolescent conflicts. Drugs were used to deal with feelings of depression, alienation, low self-worth or confused personal identity. This group turns to drugs to avoid psychological pain rather than for pleasure.

What To Do

To circumvent each succeeding generation of adolescents from being initiated into drugs, preventive efforts must be instituted earlier. Drug education must begin prior to adolescence. As the legal prescriber and dispenser of drugs, the physician is in a position to define and utilize primary prevention.

Figure 2

1. Physicians must avoid prescribing drugs for minimal stresses and frustrations of adults. Otherwise, by identification, their children may become sensitized to drug use in coping with adolescent stresses.
2. Physicians should not oversupply drugs. One recent survey revealed an average of seven different prescription drugs per home medicine cabinet. Most were outdated. Often these serve as a source of a first drug experience to adolescents. Also, they are the prime vehicle of adolescent suicide attempts.
3. For young children, the physician needs to guide the parents to emphasize specificity for drugs in a matter of fact way rather than dwelling on an enticing quality of taste or color. Manufacturers have already done this.
4. For teenagers, the physician may be the unknowing source of a first drug experience by dispensing drugs such as barbiturates in routine orders.

It has been found in this Center that the young teenager deeply caught in peer group drug usage often has more than he can cope with in the situation and wants to be rescued. He may present himself in a round-about way for discovery, such as going to the school nurse for an abscess caused by drug injection. If a drug problem then comes to the physician's attention, the most rapid course of action is a diagnostic interview with the teenager and his family. For a minimal problem, counseling by the family physician may suffice. For continuing drug use, individual psychotherapy or direct referral to an outpatient drug treatment center is indicated. For the severe drug user, a residential treatment center should be considered.

Conclusions

A study of current drug users referred to the PARC Program at Mt. Sinai Drug Treatment Center shows that the greatest number are adolescents. However, current figures show a decrease in total numbers as compared with figures 16 months ago. This is in spite of the Center being more widely known at present.

Although there is a decrease in total number, the severity of individual drug problems in the 17 to 19 year old group seen in this clinic is greater. The largest source of new cases is in the 12 to 15 year old group. At present these are transitory cases. This age group may prove to be the endemic reservoir of future drug problems.

Thus, although in considering total numbers, the drug epidemic may be waning, serious potential hazards to youth continue to exist. New complications are being reported, as for example, strokes and persistent dyskinesias in adolescent drug users.^{7,8} The psychosocial problems that the vulnerable adolescent may seek to resolve by drug use remain unsolved.

If drug abuse in future adolescents is to be circumvented, the focus for physicians, educators and parents must be on childhood. The child must be taught not only to be discriminating about useful drugs, but acquire concepts of how to cope with stresses and tensions that may later lead to drug abuse. Indications are of a return to alcohol—the licit drug—in the high school population. Drug education in childhood must also focus on that established drug problem.

St. Paul Children's Hospital

Dr. Richard E. Sand, pediatrician, is the new Chief of Staff for the St. Paul Children's Hospital Medical Staff.

At the Hospital's annual meeting, Dr. Robert T. Dooley was voted Chief of Staff-elect and Dr. Krishna M. Saxena was elected Secretary-Treasurer of the Hospital's 280-member Medical Staff.

Others elected were Dr. Robert W. Geist and Dr. John W. Reynolds to the Executive Committee of the Medical Staff; Dr. Thomas L. Huseby to the Liaison Committee of the Board of Trustees; and Dr. Stanley J. Antolak, Dr. Thomas P. Keenan, Dr. Ronald M. Lampert and Dr. R. James Vaccarella to the Medical Care Committee.

Management of Adolescent Suicide Attempts

DAVID W. CLINE, M.D.

THE RATE OF ADOLESCENT suicide attempts and adolescent suicides has dramatically increased over the past decade. In 1969, it was reported that among youth from age 15-24, suicide is the third highest cause of death although absolute numbers are low.¹ Among the college student age group suicide seems to be the second highest cause of death. All these figures are judged to be under-reporting, since suicide still casts a stigma on survivors. Coroners attempt to report accidental death when suicide was, in fact, the case. Automobile accidents of a single car type may be suicides that are undetected. Ross² estimated that for college students the incidence of suicide is 10.5 per 100,000. Jacobzimer³ estimated the total number of suicide attempts in the American population below 20 years of age to be 60,000 per year. He gave evidence that the figure is rising. The University of Minnesota Hospitals' Adolescent Young Adult Psychiatric Service has from 50-65% of its 20-bed population persons who attempted suicide.

There have been numerous studies on the prediction of suicide in patients by studying predisposing factors. All the studies using psychometric instruments revealed no consistent patterns in adolescent suicidal patients. Unlike adults the suicidal adolescent is not prone to demonstrate particular behavioral change prior to suicide attempts.⁴ Most suicidal acts in adolescents are impulsive behaviors that result from a family quarrel or a boyfriend-girlfriend dispute. In the psychotic adolescent one can identify suicidal intent more clearly. For example if the youngster reports that he hears voices from God telling him to kill himself, he is obviously a serious suicidal risk. Suicidal intent in the schizoid or paranoid adolescent is more difficult to detect. Psychotic adolescents

should be thought of as suicidal until they are well enough understood to rule out this possibility.

A consistent finding was made by Moss and Hamilton⁵ regarding family as an integrated unit in suicide or suicide attempts. They found that in 95% cases of suicide, there was death or loss of an individual close to the patient. These investigators conducted a study evaluating death trends in two groups of control subjects and an experimental group. A control group of 50 patients not considered potentially suicidal were selected for age, marital status, diagnosis at the time of hospital admission. Another control group were those patients who were considered potentially suicidal, but who had never attempted suicide, the experimental group were patients who had attempted suicide. Whereas the death trend was found in only 40% of each of the control groups, the experimental group reached the 95% level. They found that the death of a parent in suicidal patients was four times as frequent as in non-suicidal patients. Schrut⁶ found among 50 victims, age 15-20, that two-thirds of the parents had been divorced or separated prior to the incident. Approximately 50% of the patients had previously reported long and bitter clashes with parents. It was also found that suicidal ideation was common in the parents of the suicidal victims. In five of 14 patients, suicide was precipitated by rejection from a boyfriend. Another striking finding was that parents had often communicated overtly or covertly to the patient that he was unwanted during this period of his life, or even at birth. Sabbath⁷ describes the adolescent-suicidal patient as being an "expendable child," and Rosenbaum and Richman⁸ describe the role of hostility and death wishes from the family and significant others in suicide. It is clear from previous research that whenever an adolescent attempts suicide it is a manifestation of emotional instability and thorough evaluation is necessary.

Dr. Cline is Assistant Professor, Department of Psychiatry, University of Minnesota Medical School, Minneapolis, Minnesota.

See editorial, page 133.

Assessment of Suicidal Behavior

The recognition of suicidal potential in the adolescent will enhance the physician's ability to deal with this problem effectively. Depression is seen less consistently in adolescents as typified by the symptoms of depression in adults. If it is present, it is a valuable sign of possible suicide intent. Others have suggested that depression has special characteristics in teenagers and is just not recognized. A depressed teenager may talk about feeling sad, hopeless, "turned off," or blue, or may say nothing at all. Others may resort to somatic complaints, such as excessive fatigue, inability to sleep or loss of appetite. An overt manifestation may be the adolescent's inability to concentrate, which is best reflected in school grades. Depressive equivalents may also be manifested by marked change in behavioral patterns to include running away from home. Another common manifestation of suicidal intent, especially in girls, is a school theme or note that expresses the possibility of suicide or a wish for death.

Any suicidal threat or attempt should be taken seriously. Notes, gestures, or essays may merely be manipulative attempts, but some are not. A healthy teenager does not dwell on these themes. If the physician thinks there is a possibility of suicidal ideation in an adolescent patient, he should question the patient regarding that possibility. Many teenagers are then willing to discuss their hidden thoughts. The youngster who has not had a suicidal thought may answer the question with a qualified "No." Such an answer has little meaning since most people have had thoughts about dying at one time or another. It is important for the physician to evaluate the response of the adolescent in regard to this matter. It is most important to establish good rapport with the patient, since good rapport continued over an extended period of time can be good insurance against actual suicide.

When a suicidal attempt has been made, it is important for the physician to gather sufficient data as to the method of attempt, predisposing factors, family background, and adjustment of the patient in the culture at large. There are some objective criteria for evaluating the seriousness of suicidal intent. The method used for the attempt is one example. Usually, the more serious the method, the more serious the intent. Such things as shooting oneself, running in front of an

oncoming automobile, or jumping from high places are examples of serious attempts. Cruel, bizarre self-mutilative attempts are usually found in seriously psychologically disturbed adolescents. Slitting one's throat or stabbing oneself in the eye are examples. Suicide in which there are clear attempts for the act to be discovered are not usually serious. Other rules that are not infallible truisms are: If the patient is grateful or significantly relieved following the suicide attempt, the attempt itself would appear less serious. If the patient is resentful at the fact that he was found and revived, the attempt was a serious one and, furthermore, the prognosis is poor. Suicide attempts that involve injury of another person should always be taken seriously.

Management

When a suicide attempt has been made, some immediate problems must be attended to. Risk to the patient's life must first be assessed. This means immediate medical management of life-threatening possibilities. Induced emesis, gastric lavage, control bleeding, monitoring blood pressure, respiration, fluids and electrolytes are all important medical procedures that may be necessary. After the patient has made a physical recovery, the question of whether further psychiatric hospitalization is necessary must be determined. Since psychiatric evaluation is necessary in all suicide attempts, this can often best be facilitated on an open psychiatric ward. Moss and Hamilton⁵ have described three phases of recovery following a suicide attempt. In the acute phase, the patient is often panicked, perplexed, and confused by his behavior. At this time the patient needs protection and relief from anxiety, hopelessness, and most important of all, restoration of relationships with others. This is best provided in an open psychiatric or medical ward community. Constant observation is necessary even when the patient wants to be alone. He needs reassurance by the presence of others. Sometimes, face-saving maneuvers are necessary to help reintegrate the family with the patient. Family counseling in regard to the problem is helpful. Friends and relatives need to be coached on how to approach the patient, emphasizing the need for an accepting concerned attitude. In the convalescent phase, the patient becomes more comfortable in the hospital and this is the phase of active psychotherapy. This may be the first critical period since the patient

may want to deny the significance of his act and thus hide the real problems that induced it. This has been called a flight into reality which produces serious complications in 25% of all cases, i.e. further suicide attempts if the patient were to suddenly leave the hospital, denying that he had any problems. It should be noted that families often wish to deny the impact of a suicidal gesture, since they too may be reluctant to acknowledge the emotional turmoil creating the suicide attempt. It is important during this convalescent phase that psychological problems encountered by the patient be explored with some resolution.

During the third phase, the recovery phase, the patient is back in contact with his environment. This is another critical time, since in 90% of patients studied Moss and Hamilton,⁵ the suicidal drive was reactivated when the patient came into contact with the family and community where the illness began. For example, four-fifths of all reactivations of suicidal drive occurred when the patient had been discharged or was on an overnight pass to home. What is important in this phase is continuity of the therapeutic relationship. Forewarning to the patient that such reactivation may occur is important and close support and availability of the therapist is essential to good outcome.

It is important to point out that the physician

need not be the only therapist for the adolescent who has made a suicide attempt. Office nurses or specially trained mental health care personnel can be of great value in the personal therapeutic contract necessary to manage these problems. Studies by Rioch⁹ and Cline¹⁰ have shown the capabilities of such personnel in efficaciously conducting psychotherapy.

Successful outcome in adolescent suicide attempts has most often been attributed to active intervention in the patient's home environment. In this regard it is important to help the family and relatives gain insight into possible hostility and rejection that they may have towards the patient. All of the therapeutic endeavors, without exception, involve the therapist initially being very supportive and treating the patient with care, concern and protection.

Suicide is not always preventable. In the event that suicide does occur, the physician can be helpful to the family in accepting the death in the same way that he is when death occurs from other causes. As important, the physician should attend to his own needs over the loss of a patient under his care which usually produces guilt and anger. Frank discussion with one's trusted medical colleagues over the event is often a very helpful procedure that casts realistic light upon the suicide event and can be instructive in management of future suicide problems.

Two Minnesota Specialist Admitted to American College of Cardiology

Two Minnesota doctors, Fredarick L. Gobel, Minneapolis and Gerald T. Gau, Rochester, have been granted Fellowships in the American College of Cardiology, the national medical society for specialists in cardiovascular diseases. The doctors are among a group of 94 from United States and Canada recently admitted this fall to the College's highest membership classification.

The Minnesota doctors, as well as the other new Fellows, have fulfilled stringent membership requirements based on years of practice and specialty certification.

Kyphosis and Postural Roundback Deformity

in Children and Adolescents

DAVID S. BRADFORD, M. D., JOHN H. MOE, M.D. AND
ROBERT B. WINTER, M.D.

AMONG THE DEFORMITIES which may arise during childhood and adolescence, kyphosis remains one of the most neglected. Parents and even physicians may recognize the presence of a roundback curvature of the spine but may pass it off lightly as a "problem of poor posture." Overzealous urging of the child to hold up his shoulders

results in little more than mutual irritation between the parent and child, the slumped shoulders being the result and not the cause of the kyphosis. Early recognition and proper treatment of these patients can be expected to produce a superior result not only in correcting deformity but also in alleviating back complaints (Figures 1 and 2). The purpose of this paper is to describe this disease process, and to present a plan of management.⁴

Etiology

Juvenile kyphosis was a vague concept until

David S. Bradford, M.D. is Assistant Professor.

Figures 1 (left) and 2 (right)—Xrays demonstrating 14-year-old patients with Scheuermann's kyphosis, measuring 82 degrees from T2-T11. Vertebral wedging of T7 is nine degrees. Vertebral end plate irregularity is also demonstrated. Following Milwaukee brace treatment for two years, wedging has gone and kyphosis has decreased to 45 degrees.

1920 when Holger Scheuermann⁶ first demonstrated radiographically that the deformity was caused by wedge shaped deformities of the vertebra. In 1964 K. Harry Sorensen⁸ further defined this concept and suggested that Scheuermann's disease should be taken to mean a kyphosis including three adjacent vertebra with wedging of five or more degrees. The etiology of Scheuermann's juvenile kyphosis remains unknown. The speculations outlined in the literature are as diverse as the authors who have written about them. Scheuermann, in 1921,⁵ proposed a disease process caused by avascular necrosis of the cartilage ring apophysis of the vertebral bodies. With the onset of avascular necrosis of the vertebral body, growth inhibition and ultimately kyphosis developed. Bick and Copel in 1951,¹ however, noted that the limbus, or ring apophysis, was not connected to the growth plate and therefore contributed nothing to the longitudinal growth of the vertebra. Schmorl, in 1930,⁷ suggested that herniation of the intervertebral disc material through the growth plate produced the kyphosis. These so-called Schmorl's nodules may

occur in patients who do not have Scheuermann's disease. Muscle disease, hereditary, endocrine abnormalities, growth imbalance, vitamin deficiency, and infections have been suggested as important etiologic factors but these factors remain unproved.

Clinical Description⁸

There are no definitive studies concerning the early pathogenesis of Scheuermann's disease. Other than increase in thoracic kyphosis, radiographic changes are not prominent until the child reaches ages ten to twelve. The incidence of Scheuermann's disease in most reported series would appear to be from two to six percent of the population, with males and females being equally involved. A family history of kyphosis is often positive but a genetic pattern has not been confirmed. The symptoms are frequently vague. The patient sometimes complains of pain or fatigue at the apex of the kyphosis but this is usually mild and may be overlooked unless specific inquiry is made. On examination, thoracic kyphosis with lumbar lordosis will be apparent (Figure 3). The prone hyperextension test is of great value in judging the mobility and degree of fixation of the kyphosis (Figure 4). Direct tenderness and muscle spasm may be elicited over the apex of the curve, and an associated scoliosis visualized in approximately 40% of the cases. The pectoral and hamstring muscle groups often prove tight. Rarely, neurological examination may reveal a spastic paraparesis. This is usually secondary to cord angulation at the apex of the curve.

Xray

Xray evaluation must be thorough. A lateral Xray of the spine with the arms parallel

Figures 3 (left) and 4 (right)—Kyphosis is demonstrated, which on prone hyperextension decreases markedly. This is also a useful exercise to aid in correcting the kyphosis. See text.

to the floor with the hands resting on a support is most helpful in evaluating the curvature. A standing fourteen by thirty-six inch Xray of the spine is essential in order to rule out an associated scoliotic curvature. A supine hyperextension lateral of the thoracic spine using a polyurethane plastic wedge placed at the apex of the curvature facilitates this exposure and provides important information concerning the mobility of the curve. Finally, a hand Xray should be obtained to assess the extent of skeletal maturation.³ The degree of kyphosis, lordosis, and vertebra wedging is then calculated. The angles are outlined by marking the end vertebra or that vertebra which is maximally tilted into the curve and drawing a perpendicular line to the end plate. The angle thus formed is considered to be the kyphotic angle. The sacrum is considered to be an end vertebra for the measurement of lordosis (Figure 1). Vertebral wedging is outlined in a similar fashion.

Early characteristic findings of Scheuermann's disease include wedging, Schmorl's nodules, irregular end plates, and mild scoliosis (10 to 20 degrees) with or without rotation. Although per-

sistent vascular grooves in the vertebral body has been stated to be of importance in the diagnosis as well as pathogenesis of this disease, we have not found this to be the case. Late radiographic changes include concave anterior borders of the vertebral bodies, a flattening of the vertebra giving an increase in anterior-posterior dimension, synostosis and exostoses between the bodies (Figure 5). One should assess skeletal age not only by the hand Xray but also by noting the maturation of the iliac crest apophysis and the vertebral ring apophysis. The best radiographic criteria for the diagnosis of Scheuermann's disease has proven to be evidence of irregular end plates and vertebral wedging along with an increase in the normal thoracic kyphosis. Normally the thoracic spine is kyphotic and the lumbar spine, lordotic. Accurate control studies demonstrating the normal range for these angles are unfortunately not available. From limited unpublished studies in our department we have felt that kyphosis definitely increases with age and that the upper limit of normal in the adult appears to run between 35 to 40 degrees.

Differential Diagnosis

Most authors have emphasized the problems occasionally encountered in differentiating kyphosis from infectious spondylitis. However, with a thorough clinical and laboratory evaluation, as well as tomography of the spine, the true diagnosis should be readily established. Traumatic injuries to the spine occasionally present a confusing picture but usually only one vertebral body is involved, while in Scheuermann's disease many vertebra are involved. Osteochondrodystrophy, such as Morquio's and Hurler's disease, as well as osteomyelitis, tumors, and congenital kyphosis,

Figure 5—Late radiographic changes of Scheuermann's kyphosis are visualized: wedging with concave anterior vertebral borders, synostosis and exostosis.

Figure 6—Colrel traction on the bent Bradford frame.

may be considered in the differential diagnosis. These rarely pose much of a diagnostic problem. Lumbosacral anomalies should always be ruled out. Spondylolisthesis at L5-S1 can produce a severe lumbar lordosis and consequently a compensatory thoracic kyphosis. These patients may be completely asymptomatic except for the round-back deformity.

Complication of Scheuermann's Disease

A kyphosis less than forty degrees is infrequently of cosmetic significance. If the curvature becomes greater the clinical deformity will be more pronounced even in the obese individual. Deformities above seventy degrees are quite noticeable and because of an increased compensatory lordosis and forward protrusion of the cervical spine they present a cosmetically objectionable appearance. Curves of this magnitude may increase even after skeletal maturation is completed. Pain and fatigue at the apex of the kyphosis is present in approximately one-half of the patients

before they reach age twenty. This is mild and usually not disabling. After maturity the incidence of thoracic pain seems to decrease but in some patients it may be disabling. The incidence of low back pain does not seem to be any higher than that in the normal population. Rarely signs and symptoms of upper motor neuron disease can be associated with the kyphosis. A spastic paraparesis may develop secondary to cord compression or a herniated thoracic intervertebral disc. One should always carefully examine the AP Xray of the thoracolumbar spine to be sure that widening of the interpedicular space has not occurred. Spinal epidural cyst can be associated with the classical radiographic changes of Scheuermann's disease as well as a widened interpedicular space.

Treatment

Treatment of juvenile kyphosis relies on an exercise program, a Milwaukee brace, traction, Risser antigavity casting, and surgery (Figures 6, 7, 8). The Milwaukee brace is the treatment of

Figures 7 (left) and 8 (right)—The Milwaukee brace as used for the treatment of kyphosis. Notice that the double uprights contain split kyphosis pads directed against the apex of the gibbus. The occiput pads fit under and not above the occiput. The throat mold touches the neck but the patient can raise the chin one finger breadth from it with neck extension. A turtle-neck shirt can completely hide the neck piece of the brace.

choice in a growing child with a flexible curvature. If the curve is rigid and the patient has finished growth, little improvement in the kyphosis or wedging can be expected. It may prove difficult in the young juvenile to differentiate Scheuermann's disease from a postural flexible roundback deformity. Frank radiographic changes of Scheuermann's disease, ie: wedging, may not develop until after the child reaches adolescence. One may wonder in fact if a true flexible postural roundback may develop into a structural kyphosis with vertebral wedging. Therefore this problem poses not only a diagnostic but also a treatment dilemma. It is our impression that end plate irregularity is one of the earliest radiographic features of Scheuermann's disease. This may be demonstrable long before vertebral wedging is apparent. On the other hand it appears that a pure postural roundback deformity untreated may develop into a rigid kyphosis with wedged vertebra. The treatment of either problem, therefore, would depend on the severity of the deformity and the type of radiographic changes in the vertebra. A young child with a supple roundback may be initially treated with exercises alone (Figures 9 and 10).

However, any progression of the kyphosis should be managed with a Milwaukee brace. The patient with radiographic changes of Scheuermann's disease with vertebral wedging is best managed with a Milwaukee brace from the onset. The use of the Milwaukee brace combined with a carefully planned exercise program can be expected not only to overcome the degree of vertebral wedging, but also decrease the angle of the kyphosis by forty to fifty percent of its pre-treatment value. The brace must be properly fabricated, worn twenty-three hours a day, (the patient sleeps in the brace, is allowed one hour out of the brace per day for skin care and personal hygiene), and carefully checked by the physician on each follow-up visit. On the initial visit, if a kyphosis appears rigid as determined by the hyperextension Xray, a two-week period of traction in the hospital on a reverse Bradford bed frame is carried out followed by the application of a Risser antigravity cast. The cast may be changed several times in order to obtain more correction while the Milwaukee brace is being fabricated. When the brace treatment has begun, a specific exercise program is initiated by the physical therapist. This is directed at de-

Figures 9 (left) and 10 (right)—Xrays of a patient with a pure postural roundback. Treated by exercises alone. Note absence of vertebral end plate irregularity, and wedging.

creasing lumbar lordosis, overcoming muscle contractures by muscle stretching when necessary, and correcting the kyphosis by thoracic hyperextension (Figures 4, 11, 12). The patient is checked with repeat Xrays in the brace at four month intervals. When skeletal maturation has approached completion the patient may be gradually weaned from the brace. The weaning process initially consists of short periods (two to three hours) out of the brace during the day progressing finally to brace

wearing at night only. Xrays both in the brace and out of the brace for the specified period of time are carefully compared. Loss of correction suggests the weaning has been too rapid and the period of time out is decreased accordingly. Total brace wear, including night time wear only, averages three to four years (Figures 13, 14, 15). As a practical guideline, we have found that once the kyphosis and wedging are corrected, weaning from the brace can be rapidly carried out.

Figures 11 (left) and 12 (right)—Lumbar lordosis is corrected by pelvic tilting exercises. Notice how in Figure 12 the lordosis has decreased as a result of tilting the pelvis and flattening the lumbar spine against the examining table.

Figures 13 (left), 14 (middle), 15 (right)—End result on patient in Figure 3. Milwaukee brace worn full time for approximately one and a half years. Original kyphosis 55 degrees; corrected to 17 degrees.

Rarely, surgery may be necessary. The indications include severe kyphosis in a patient who has completed growth, severe and disabling back pain in the area of the kyphosis which is unresponsive to conservative management, and neurological signs and symptoms secondary to the kyphosis. Surgery consists of posterior spine fusion, Harrington rod instrumentation, with iliac crest bone grafting, followed by plaster immobilization for a period of nine months (Figures 16 and 17). We have generally felt that the incidence of pseudarthrosis and loss of correction was minimized by keeping the patient supine for four months following surgery. Anterior fusion may be necessary in those cases with kyphosis greater than seventy-five to eighty degrees or in those patients with an asso-

ciated neurological deficit requiring anterior cord decompression.

Summary

Juvenile kyphosis has unfortunately remained a poorly recognized entity. It is felt that earlier recognition and treatment of this problem can prevent progressive deformity, disabling back pain, and neurological complications. An outline of treatment is presented which the authors have found to be highly effective in the management of patients with this disorder.

Acknowledgment

We would like to express our appreciation for the help and support of the Gillette Children's Hospital staff, particularly Miss Jean Conklin and Mr. Ned Gardner, for their cooperation in facilitating this work.

Dermatoses of Adolescence

BRUCE J. BART, M.D.

THERE ARE NO DERMATOSES exclusive to the adolescent period. Some skin conditions, however, are commonly seen in this age group. Others, previously infrequent in preadults, are now seen in increasingly numbers relating to increased sexual promiscuity and use of drugs.^{1,2}

Acne

Acne is the most common dermatosis in the adolescent period; indeed, its development may be considered physiologic. The emotional impact, particularly in those persons with the pustular, cystic, and scarring varieties of acne, may be devastating.

Modern concepts of the mechanisms of this condition have led to more rational and successful treatment and control.³ Certain bacteria in pilosebaceous areas produce lipolytic enzymes, causing breakdown of sebum. Fatty acid end-products, primary irritants to ductal and follicular walls, produce the inflammatory reaction clinically appearing as the inflamed "papule," pustule, or pseudocyst.

Systemic antibiotics, particularly the tetracyclines, are most helpful in suppressing these lipase-producing bacteria. Topical agents such as Vitamin A acid, Benzoyl peroxide lotions, and sulfur and resorcinol lotions help to remove comedones and prevent further obstruction of pilosebaceous structures. Surgical expression of comedones, exposure to ultraviolet irradiation, injection of inflamed pseudocysts with corticosteroids, systemic corticosteroid drugs for acutely inflamed conditions, and dermabrasion for unsightly scars are other useful treatment methods.

Dietary factors in acne may influence the course of the condition. Patients are advised to eat a well balanced diet. Advice regarding cosmetics, skin hygiene, and scalp care is also important.

Dr. Bart is Chief, Department of Dermatology, Hennepin County General Hospital, Minneapolis, Minnesota and Assistant Professor, Department of Dermatology, University of Minnesota, Minneapolis, Minnesota.

Warts

Warts are tumors of skin or mucous membranes caused by viral agents.⁴ They may be found in all age groups and affect any cutaneous surface. Warts probably occur with greatest frequency in the childhood and adolescent periods. Areas of predilection are the hands, feet, and genitalia.

Warts spread by inoculation of virus into the skin surface and may be transferred from person to person by direct contact or indirectly from fomites. After entry of the virus into the skin incubation may take several months until the wart appears.

Treatment of warts include studied neglect (many warts disappear spontaneously after a few months or years), proprietary peeling creams, topical chemosurgical agents, cryosurgery with liquid nitrogen, electrosurgery, surgery, local injections and irradiation with low-voltage Xrays. None of these methods is predictably successful. Immune antibodies to wart virus have been measured in patients with resolving warts and are probably an essential part of successful resolution.^{5,6}

Venereal Warts

Venereal warts or condyloma acuminata affect the genital or perianal and anal areas. Often spread by sexual contact, the incidence of this

Fig. 1—Condyloma acuminata involving penis.

condition is increasing, particularly in sexually promiscuous adolescents and young adults; both from homosexual and heterosexual encounters (Figures 1 and 2).

Fig. 2—Condyloma acuminata of anal area in homosexual.

Treatment includes painting the warts with 25% podophyllum resin, electrosurgery or surgery. Topical Fluorouracil may clear stubborn warts.

Molluscum Contagiosum

Molluscum contagiosum is a form of wart tumor also caused by cutaneous inoculation of viral bodies. These warts present as smooth, pink, dome-shaped umbilicated papules (Figures 3). Any cutaneous surface may be affected, but sites of predilection include the face, hands, chest, axillary areas, genitalia, and perianal areas. Children and teenage persons are most commonly afflicted. Molluscum warts may also spread by sexual contact.

Fig. 3—Molluscum contagiosum.

Treatment includes curettage, chemosurgery, cryosurgery, and electrosurgery.

Herpes Simplex

Recurrent herpes simplex is a common cutaneous viral infection in all age groups. Increasing genital infections (herpes progenitalis) may relate to increasing promiscuity⁷ (Figure 4). Recurrent grouped vesicles, sometimes painful, erode and become crusted in a few days. Differential diagnosis must include primary syphilis. Smears may reveal the characteristic giant cells and inclusion bodies and viral cultures may identify the viral agent.

Treatment with topical idoxuridine⁸ or photodynamic inactivation with dyes such as neutral red dye⁹ may help resolve and prevent recurrent infection.

Fig. 4—Herpes simplex progenitalis.

Pediculosis Pubis

Infestation with phthirus pubis or the "crab louse" may cause much itching and secondary infection in the pubic or other hairy areas. Usually spread by sexual contact, this infestation may accompany other venereal diseases. Current increased promiscuity has caused a resurgence of this infection.

Diagnosis is confirmed by finding the small, dark gray louse at the base of the hair and locating the nits attached to the hair shaft (Figure 5).

Fig. 5—Pediculosis pubis showing small brown lice at base of hairs.

Treatment with gamma benzene hexachloride (Kwell cream, lotion or shampoo) is effective.

Venereal Diseases

It is not the purpose of this paper to discuss the usual venereal diseases. Syphilis, gonorrhea, chancroid, lymphogranuloma venereum, and granuloma inguinal may all certainly develop in adolescents. These infections must be considered not only in all genital ulcerations and vaginal and urethral discharges but in perianal and anal sores, venereal warts, proctitis, mouth and throat lesions, and suspicious skin eruptions.¹⁰

Skin Markers in Drug Abuse

Cutaneous manifestations in the drug abuser, particularly from injections of heroin, may be valuable clues to the physician.^{11,12} In the adolescent who appears disoriented, incoherent, or comatose, locating such skin signs may be crucial.

Skin infections at sites of injections of drugs include impetiginous and ecthymatous lesions, ab-

cesses or ulcers. Contaminated needles or materials added to dilute the drug may cause the infection. Tissue reaction to injected materials may also lead to secondary infection. This is particularly seen with quinine and sugar fillers. Occasionally severe necrosis ensues.¹³ Ulcers may develop over sclerosed or infected blood vessels. Linear hyperpigmented streaks on antecubital fossae, forearms, wrists, hands, and feet may represent needle tracks. Discrete hyperpigmented depressed skin lesions develop in areas of subcutaneous injections of heroin, the so-called "pop" scars. These may result in hypertrophic scars or keloids.

Chronic edema of the hands from thrombophlebitis or lymphedema may follow recurring infections. Generalized or localized pruritus occasionally follows heroin injection. Jaundice and gynecomastia secondary to hepatitis may also develop.

Other skin signs include: increased pigmentation in sun exposed areas, linear bands of pigmentation from pressure of a tourniquet, excoriations, tattooing of skin, and thermal burns from cigarettes.¹²

Conclusion

Contemporary life styles have influenced the incidence of many skin diseases of the adolescent. Several reports indicate increased incidence of syphilis, gonorrhea, and chancroid in the adolescent. To these must be added warts, condyloma acuminata, molluscum contagiosum, herpes simplex, and pediculosis pubis.

Drug abuse, particularly of those drugs injected into the skin or blood vessels, may be suspected with certain patterns of skin infections or scarring. Skin findings may contribute an important clue to the clinician in diagnosing drug-related problems.

Historic Hospitals

THE MASSACHUSETTS GENERAL HOSPITAL

The Bulfinch Building, Massachusetts General Hospital. The Ether Dome can be seen protruding above the four central chimneys. (Courtesy Massachusetts General Hospital.)

Visitors to Boston are often invited to admire a number of historic buildings designed by Charles Bulfinch, the area's first native-born architect. The last of Bulfinch's buildings in Boston, completed in 1824, is the Massachusetts General Hospital (MGH). While the first American hospital to boast of plumbing and central heating, its most famous feature is a skylighted surgical amphitheater familiar throughout the world as the "Ether Dome". Here on October 16, 1846, one of the hospital's cofounders, Dr. John C. Warren, excised a tumor of the jaw in the first public demonstration of ether anesthesia. The Ether Dome, now designated by the Department of the Interior as a national historic landmark, is still used as a hospital conference room.

The Bulfinch Building was situated in old Boston's West End on the Charles River Flats, about 40 yards from the river, where patients were often transported by boat. The Flats have since been filled in and the Bulfinch Building is surrounded by a modern 1000-bed complex which allows the MGH to maintain its position among the world's foremost hospitals.

While the hospital's history is not the lengthiest in the United States, it may well be the most illustrious. Besides pioneering in anesthesia the MGH led in the introduction of antiseptic and aseptic surgical techniques in the United States. In the 1880's an MGH pathologist, Dr. Reginald H. Fitz, was the first in modern times to identify the source of appendicitis, and he gave the disease its name. The hospital's surgical staff led in the development of its primary treatment, the appendectomy.

Other medical leaders associated with MGH, and the list is far from complete, were: Dr. James H. Wright of Wright's Stain fame, Dr. J. Howard Means, pioneer in diagnosis and treatment of thyroid diseases, Dr. Fuller Albright, investigator of hyperparathyroidism and other metabolic diseases of bone, and Dr. Richard C. Cabot, who developed at the hospital the world's first social service department. Another of Dr. Cabot's contributions was the development of the clinical pathological conference as a method of medical teaching. The Clinical Path Conferences of the Massachusetts General are not only the oldest series, but, are still published in the *New England Journal of Medicine*, the most widely read in the world.

Letters to the Editor

MINNESOTA MEDICINE November color photo and story, that's corn to me . . . not wheat. How many notes like this came in? It proves the readers look—if they know the difference.

Burton P. Grimes, M.D.
St. Peter, Minnesota

Dr. Wendland, I fear, is going to catch some heat on his "wheat," so beautifully photographed on the November MINNESOTA MEDICINE cover. Any Minnesota doctor who grew up on a farm or practiced in a rural area will quickly spot it as corn.

The title too, is slightly misleading; temporally speaking. Judging by the length of the shadows of the corn shocks, and the number and color of the sumac leaves in the foreground it should be "October Song."

Some of the heat must of course be directed to the editor of the caption.

L. H. Hammar, M.D.
Mankato, Minnesota

In the last issue of MINNESOTA MEDICINE for November 1972, there is a beautiful photograph on the cover by John P. Wendland entitled "November Song." On Page 1015 in this issue, there is an editorial about the photograph and it is stated "this particular field of wheat as this method of harvesting wheat is disappearing from the farm scene. Most of this is done by combine."

Somehow here a field of corn became confused with a field of wheat. The picture on the cover is obviously a field of corn that has been cut and placed in shocks.

Wheat is harvested in August and is sometimes placed in shocks but they have an entirely different appearance. A wheat field does not appear in rows as does a corn field.

I know Dr. Wendland and I can't believe that he could be this confused or possibly so much in need of a refraction.

A. G. Sherman, M.D.
Albert Lea, Minnesota

If the November cover photograph "November Song" isn't a field of corn shocks, I'll quit eating cracked-wheat bread and switch to corn pone.

D. A. Johnson, M.D.
Litchfield, Minnesota

It is encouraging to see that not all doctors are "city slickers" and that a great many of them apparently know a shock of wheat from a shock of corn.

Apparently there is a lot of interest in the cover of MINNESOTA MEDICINE also.

I wish that we could say that we had called the shocks wheat just to see how many readers were paying attention, but alas, I had not carefully checked the slide for several years and in my telephone diagnosis called it wheat. It just shows you the danger of giving advice over the telephone. As an old Nebraska farmer, it is obvious that the shocks are corn.

John P. Wendland, M.D.
Minneapolis, Minnesota

Dr. Reece's article on "Healthcaremanship"* was excellent and timely indeed. Equipped with new knowledge on Windfoggery, Double Dawdles, and literary "Buzz Bombs," I found them in the Supplement to the same issue of MINNESOTA MEDICINE sponsored by NRMP (Northlands Regional Medical Program, Inc.). There it is written: "It (RMP) will be called upon increasingly to advance the Science of Applied Research and Development, to promote the fields of Health Care, Economics and Health Care Systems Development, and to use its multi-disciplined staffs to provide evaluation studies and consultations for other organizations."

Holy bureaucracy, I can feel the wind and cannot see for the fog. Spare me the details, please let me have it straight! What is meant by "advancing the Science of Applied Research and Development?" Do I hear a fog horn when it is said that there will be "jurisdictional changes, and RMP will undoubtedly be one of them?" I scare easily. It may mean: "Watch out, fellow, here comes the Government." But why should I scare when the "Smart Buzz Bombs" fall? Isn't it a nurse who tells me in so many words and paragraphs on Page 51 that she would like our Junior Colleges to be in charge of Continuing Education for Nurses? After all, nurses help sick people get well and also help the doctors. I work with them all the time. A nurse should not scare me by throwing "Buzz Bombs," kicking me with Saxon Sidesteps, or waylaying me with Paragraph Parries and Finishing Finesses.

When I look at this Special Issue and at the gifted people who composed it, I like to quote the Godfather: "Let's make 'em an offer they cannot refuse: Come back to Medicine. It is rewarding, fulfilling, and not dangerous at all!"

H. W. Heupel, M.D., Ph.D.
Minneapolis, Minnesota

*Minnesota Med 55:1141, 1972.

Denial of Hospital Staff Privileges

A physician was denied hospital staff membership and admitting privileges by the hospital staff. The physician in question had a poor work history along with dismissal from another hospital staff because of incompetence. The hospital staff requested current references with an evaluation of competence from the head of the hospital whose facilities had been previously used. The physician failed to furnish the requested references.

The patient then instituted an action to compel the hospital to admit her to its medical staff. The court held that the hospital was a private hospital and could refuse staff privileges on any ground it deemed sufficient.

The physician contended that private hospitals should admit any licensed physician to use their facilities. The court then upheld the hospital in their refusal to grant admitting privileges to this physician.

Theodore A. Peterson, M.D.

Rao v. Board of County Commissioners (Pierce), 497 P.2d 591 (Wash. Sup. Ct., June 1, 1972). The Citation 26:1, October 15, 1972.

Who knows what evil lurks in the mucous membranes?

Ornade[®] knows.

Each Spansule[®] (brand of sustained release capsule) contains 8 mg. of Teldrin[®] (brand of chlorpheniramine maleate); 50 mg. of phenylpropanolamine hydrochloride; and 2.5 mg. of isopropamide, as the iodide.

Knows the public's enemies — nasal congestion, runny nose, sneezing, watery eyes.

Knows what to do about them too. All through the dark night of upper respiratory difficulty, while ordinary cold remedies wear off, the decongestant, antihistamine, and drying agent in 'Ornade' fight the never-ending battle for comfort, symptomatic relief, and free airways.

Ornade[®]. Why not let it help fight your patient's cold war.

Before prescribing, see complete prescribing information in SK&F literature or PDR.

Indications: Upper respiratory congestion and hypersecretion associated with: the common cold; acute and chronic sinusitis; vasomotor rhinitis; allergic rhinitis (hay fever, "rose fever," etc.).

Contraindications: Hypersensitivity to any component; concurrent MAO inhibitor therapy; severe hypertension; bronchial asthma; coronary artery disease; stenosing peptic ulcer; pyloroduodenal or bladder neck obstruction. Children under 6.

Warnings: Caution patients about activities requiring alertness (e.g., operating vehicles or machinery). Warn patients of possible additive effects with alcohol and other CNS depressants.

Usage in Pregnancy: In pregnancy, nursing mothers and women who might bear children, weigh potential benefits against hazards. Inhibition of lactation may occur.

Effect on PBI Determination and I^{131} Uptake: Isopropamide iodide may alter PBI test results and will suppress I^{131} uptake. Substitute thyroid tests unaffected by exogenous iodides.

Precautions: Use cautiously in persons with cardiovascular disease, glaucoma, prostatic hypertrophy, hyperthyroidism.

Adverse Reactions: Drowsiness, excessive dryness of nose, throat or mouth; nervousness; or insomnia. Also, nausea, vomiting, epigastric distress, diarrhea, rash, dizziness, weakness, chest tightness, angina pain, abdominal pain, irritability, palpitation, headache, incoordination, tremor, dysuria, difficulty in urination, thrombocytopenia, leukopenia, convulsions, hypertension, hypotension, anorexia, constipation, visual disturbances, iodine toxicity (acne, parotitis).

Supplied: Bottles of 50 capsules.

SK&F Smith Kline & French Laboratories

the delicate balance

estrogen
progesterone

Clinical evidence clearly suggests that no single birth control pill can suit all women. Searle offers three pill formulations, each with a different hormone ratio and activity to cover most patients' needs.

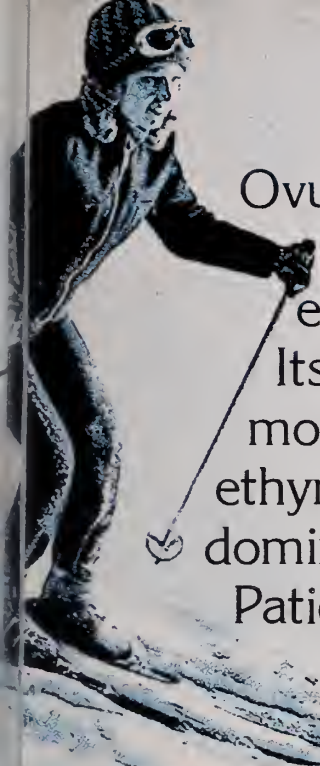

Demulen is well suited to those women for whom low-dose estrogenic activity may be preferred. Demulen has only 50 mcg. of estrogen and is moderately progestogen dominant. Intracycle bleeding, if it occurs, is most commonly seen in the first few cycles. Certain women requiring a minimal level of estrogenic activity may do well on Demulen. **for high estrogen profiles and for conservative oral contraception**

Demulen®

Each white tablet contains:
ethynodiol diacetate 1 mg/ethinyl estradiol 50 mcg.

Note: Oral contraceptives are complex medical products. They should be prescribed with care only after reference to the prescribing information.

Ovulen is a well-balanced oral contraceptive with an excellent record of patient acceptance.

Its estrogen, 100 mcg. of mestranol, is relatively moderate in activity. Its 1 mg. of progestogen, ethynodiol diacetate, gives it a slight dominance in progestational activity.

Patients having problems on other pills often do well on Ovulen. **for balanced profiles, with normal menstruation**

Ovulen®

Each white tablet contains: ethynodiol diacetate 1 mg./mestranol 0.1 mg.
Pink tablet in Ovulen-28® and Demulen-28® is a placebo, containing no active ingredients.
Both Ovulen and Demulen are available in 21- and 28-pill schedules.

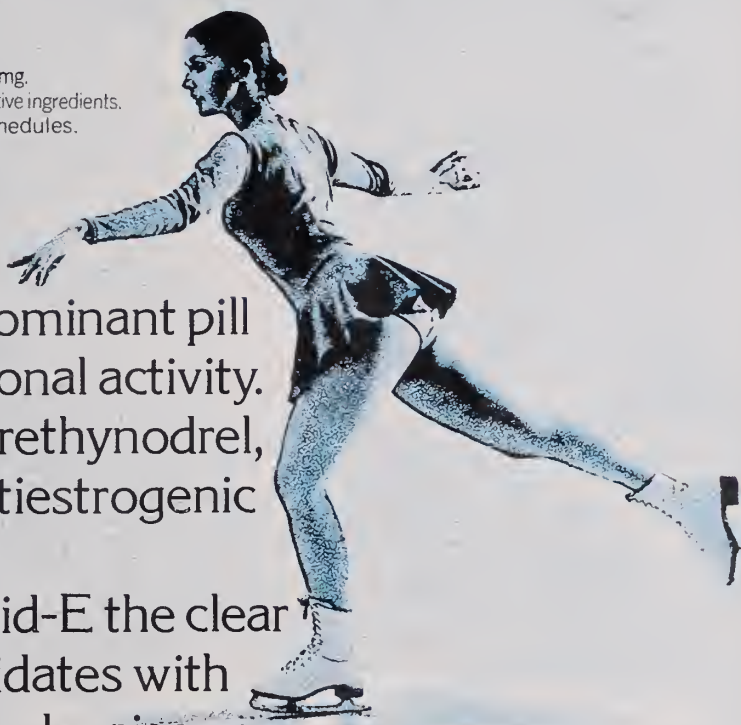

Enovid-E is an estrogen-dominant pill with low progestational activity. Its unique progestogen, norethynodrel, is estrogenic and is not antiestrogenic or androgenic in activity.

This probably makes Enovid-E the clear choice for those "pill" candidates with acne, hirsutism, masculine tendencies or apparent estrogen deficiency.

**for excessive ovarian androgen/
low-estrogen profiles**

Enovid-E®

Each tablet contains: norethynodrel 2.5 mg./mestranol 0.1 mg.

Ovulen®

Each white tablet contains
ethynodiol diacetate 1 mg / mestranol 0.1 mg

Each pink tablet in Ovulen-28* and Demulen-28* is a placebo, containing no active ingredients

Demulen®

Each white tablet contains
ethynodiol diacetate 1 mg / ethinyl estradiol 50 mcg

Actions—Ovulen and Demulen act to prevent ovulation by inhibiting the output of gonadotropins from the pituitary gland. Ovulen and Demulen depress the output of both the follicle-stimulating hormone (FSH) and the luteinizing hormone (LH).

Special note—Oral contraceptives have been marketed in the United States since 1960. Reported pregnancy rates vary from product to product. The effectiveness of the sequential products appears to be somewhat lower than that of the combination products. Both types provide almost completely effective contraception.

An increased risk of thromboembolic disease associated with the use of hormonal contraceptives has now been shown in studies conducted in both Great Britain and the United States. Other risks, such as those of elevated blood pressure, liver disease and reduced tolerance to carbohydrates, have not been quantitated with precision.

Long-term administration of both natural and synthetic estrogens in sub-primate animal species in multiples of the human dose increases the frequency of some animal carcinomas. These data cannot be transposed directly to man. The possible carcinogenicity due to the estrogens can be neither affirmed nor refuted at this time. Close clinical surveillance of all women taking oral contraceptives must be continued.

Indication—Ovulen and Demulen are indicated for oral contraception.

Contraindications—Patients with thrombophlebitis, thromboembolic disorders, cerebral apoplexy or a past history of these conditions, markedly impaired liver function, known or suspected carcinoma of the breast, known or suspected estrogen-dependent neoplasia and undiagnosed abnormal genital bleeding.

Warnings—The physician should be alert to the earliest manifestations of thrombotic disorders (thrombophlebitis, cerebrovascular disorders, pulmonary embolism and retinal thrombosis). Should any of these occur or be suspected the drug should be discontinued immediately.

Retrospective studies of morbidity and mortality conducted in Great Britain and studies of morbidity in the United States have shown a statistically significant association between thrombophlebitis, pulmonary embolism, and cerebral thrombosis and embolism and the use of oral contraceptives. There have been three principal studies in Britain^{1,2} leading to this conclusion and one³ in this country. The estimate of the relative risk of thromboembolism in the study by Vessey and Doll¹ was about sevenfold, while Sartwell and associates⁴ in the United States found a relative risk of 4.4, meaning that the users are several times as likely to undergo thromboembolic disease without evident cause as nonusers. The American study also indicated that the risk did not persist after discontinuation of administration and that it was not enhanced by long-continued administration. The American study was not designed to evaluate a difference between products. However, the study suggested that there might be an increased risk of thromboembolic disease in users of sequential products. This risk cannot be quantitated, and further studies to confirm this finding are desirable.

Discontinue medication pending examination if there is sudden partial or complete loss of vision, or if there is a sudden onset of proptosis, diplopia or migraine. If examination reveals papilledema or retinal vascular lesions medication should be withdrawn.

Since the safety of Ovulen and Demulen in pregnancy has not been demonstrated, it is recommended that for any patient who has missed two consecutive periods pregnancy should be ruled out before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule the possibility of pregnancy should be considered at the time of the first missed period.

A small fraction of the hormonal agents in oral contraceptives has been identified in the milk of mothers receiving these drugs. The long-range effect to the nursing infant cannot be determined at this time.

Precautions—The pretreatment and periodic physical examinations should include special reference to the breasts and pelvic organs, including a Papanicolaou smear since estrogens have been known to produce tumors, some of them malignant, in five species of sub-primate animals. Endocrine and possibly liver function tests may be affected by treatment with Ovulen or Demulen. Therefore, if such tests are abnormal in a patient taking Ovulen or Demulen, it is recommended that they be repeated after the drug has been withdrawn for two months. Under the influence of progestogen-estrogen preparations pre-existing uterine fibromyomas may increase in size. Because these agents may cause some degree of fluid retention, conditions which might be influenced by this factor, such as epilepsy, migraine, asthma, cardiac or renal dysfunction, require careful observation. In breakthrough bleeding, and in all cases of irregular bleeding per vaginam, nonfunctional causes should be borne in mind. In undiagnosed bleeding per vaginam adequate diagnostic measures are indicated. Patients with a history of psychic depression should be carefully observed and

the drug discontinued if the depression recurs to a serious degree. Any possible influence of prolonged Ovulen or Demulen therapy on pituitary, ovarian, adrenal, hepatic or uterine function awaits further study. A decrease in glucose tolerance has been observed in a significant percentage of patients on oral contraceptives. The mechanism of this decrease is obscure. For this reason, diabetic patients should be carefully observed while receiving Ovulen or Demulen therapy. The age of the patient constitutes no absolute limiting factor, although treatment with Ovulen or Demulen may mask the onset of the climacteric. The pathologist should be advised of Ovulen or Demulen therapy when relevant specimens are submitted. Susceptible women may experience an increase in blood pressure following administration of contraceptive steroids.

Adverse reactions observed in patients receiving oral contraceptives—A statistically significant association has been demonstrated between use of oral contraceptives and the following serious adverse reactions: thrombophlebitis, pulmonary embolism and cerebral thrombosis.

Although available evidence is suggestive of an association, such a relationship has been neither confirmed nor refuted for the following serious adverse reactions: neuro-ocular lesions, e.g., retinal thrombosis and optic neuritis.

The following adverse reactions are known to occur in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal symptoms (such as abdominal cramps and bloating), breakthrough bleeding, spotting, change in menstrual flow, amenorrhea during and after treatment, edema, chloasma or melasma, breast changes (tenderness, enlargement and secretion), change in weight (increase or decrease), changes in cervical erosion and cervical secretions, suppression of lactation when given immediately post partum, cholestatic jaundice, migraine, rash (allergic), rise in blood pressure in susceptible individuals and mental depression.

Although the following adverse reactions have been reported in users of oral contraceptives, an association has been neither confirmed nor refuted: anovulation post treatment, premenstrual-like syndrome, changes in libido, changes in appetite, cystitis-like syndrome, headache, nervousness, dizziness, fatigue, backache, hirsutism, loss of scalp hair, erythema multiforme, erythema nodosum, hemorrhagic eruption and itching.

The following laboratory results may be altered by the use of oral contraceptives: hepatic function, increased sulfobromophthalein retention and other tests, coagulation tests, increase in prothrombin, Factors VII, VIII, IX and X, thyroid function, increase in PBI and butanol extractable protein bound iodine and decrease in T₃ uptake values, metyrapone test and pregnanediol determination.

Adolescent Medicine—Where Are the Adolescents?

ADOLESCENCE IS AN overlabeled period of life. Long hair and well worn blue jeans—like a badge—quickly bring to mind the term “teenager.” Although this group may be over-identified in the population at large, medically they are overlooked. Doctors’ waiting rooms are almost devoid of teenagers, in spite of a population of adolescents numbering 30 million. Where are they to be found?

It is true that American youngsters are considered to be the healthiest in the world, yet they have pronounced medical problems. As attested to by the special articles in this issue of MINNESOTA MEDICINE, suicide is on the increase in this age group. Venereal disease has increased tenfold in the past 15 years, particularly in the adolescent group. One in six unmarried adolescent girls becomes pregnant. Drug abuse is epidemic in junior and senior high school students.

The adolescent has until recently received little attention as to specific health needs and problems. An orderly progression from pediatric care to generalized or specialized adult medical care was lacking. For the age span of 12-20 years, teenagers were either seen by their childhood physician or their parent’s physician. At present medical care for teenagers is channeled into two prevalent movements—both with their shortcomings. The first is the Adolescent Clinic and Hospital Unit. This was pioneered by Dr. J. Roswell Gallagher at Children’s Medical Center in Boston as recently as 1951. Its purpose was to integrate an understanding of the disease processes, physiology, environmental forces, as well as the intrinsic

hopes, fears and concerns intrinsic to the adolescent.¹ Dr. W. A. Daniel, Jr.,* who is also well known in this field, presents an article in this issue attesting to the need to consider the adolescent with an approach defined in terms of his specific needs. The gross deficiency of the Adolescent Clinic movement lies in that there are only 70 such units in the country. The Society for Adolescent Medicine founded as recently as 1968 has only 450 members.

The second movement is that of the Free Clinics. Current figures estimate that there are 200 in the country serving approximately 2,000,000 patients per year, chiefly the young.² The merit of these clinics lies in reaching large numbers of patients who will not go elsewhere for medical care. These clinics have evolved skills in methods of speaking the language of and communicating with youth. Their referrals are largely from other adolescents.

One of their shortcomings is that because of limited budgets and facilities they are forced to operate in a borderline way. Another is that they lack continuity of care. One prediction is that Free Clinics are an interim problem-solving mechanism and will eventually be absorbed into regular medical channels.

The adolescent by legislation now comes into greater choice of his own medical care. He can be treated without parental consent. There is one important resource readily available but rejected by many adolescents and that is the family physician. It is he who knows the previous medical history, the family history and can give continuity of care. However, according to the way the adolescent feels, this may be an interfering factor. Many

adolescents think they cannot approach their family physician for birth control information or with a pregnancy without being reproved or lectured. In order to bridge the gap and reach this group medically, it is the family physician who must show the capability to re-examine and define his approach. Whether he agrees with their point

of view or not he will have to become aware of the sincere concerns of the young—ecology, pollution, population control. He will have to develop and extend his communication skills with the adolescent. Care of the young can be distressing, but it is refreshing.

Suicide Attempts: The Wish to Live

DEPRESSIVE DISORDERS are frequently overlooked in adolescence, partly because the extremes of normal adolescent behavior often obscure and delay the recognition of clear pathology. One certain means the adolescent has of alerting others to his plight is the suicidal attempt. There are approximately six to ten suicide attempts for every actual suicide in the general population. In the adolescent age range this ratio is estimated between 50 and 100 to one.

The conscious thinking of the suicidal person is that he is in an unbearable situation from which there is no alternative means of escape. Typically, his attempt is the end stage of a long-unfolding process involving early object losses, family conflicts, faulty means of coping with stress and current precipitating events which awaken prototypal feelings of loss, worthlessness, guilt and rage. His bewilderment is reflected in the feelings of perplexity and helplessness arising in those who attempt to help him. In this issue Cline* points out the importance of taking every suicidal attempt seriously and the need to learn as much as possible about the background and present conflicts of the patient.

The suicidal adolescent needs aid in reconciling

incompatible motives: the wish to die and express his sense of basic badness and the longing to survive and demonstrate his desirability and worth. While his attempt is often viewed as expression of his loneliness and desire to die, it may also be a plea to others to convince him he is worth keeping alive. The physician can help him realize that there is hope apart from his self-destructive resolve.

In addition, the adolescent who attempts suicide has often been striving for some time to communicate with some significant persons, usually his parents, but unable because of some impasse. Parents often express total unawareness of their child's distress, or find it difficult to appreciate his degree of despair. For this reason talking with the parents is an equally important part of the therapeutic intervention. The therapist must use every available means to insure that the patient's covert communication has been openly expressed and understood, and that both parties are able to share their obstructed feelings.

As with most problems in psychiatry, the internal psychological struggles cannot be resolved practically apart from giving simultaneous attention to the struggles of human relationships.

S. Wendell Obetz, M.D.
Rochester, Minnesota

Current Dimensions of the Drug Scene

CURRENT TRENDS in drug misuse, particularly among adolescents is a matter of grave concern to all physicians, and in defining their dimensions Dr. Dorothy Bernstein* has done us a great service. No matter how often the problem is mentioned in the lay press or in professional journals, we are required to extrapolate the often sensational sta-

tistics to our own practices, wherein lie some of the most fertile possibilities for preventive action. Increased usage in the 12 to 15 year old group, and increased severity of problems in those aged 17 to 19 should alert us to more careful regulation of amphetamines and barbiturates prescribed for the parents of these young drug experimenters. since initial supplies of these drugs frequently

come from family medicine cabinets. Additional preventive efforts to help both adults and adolescents cope with ordinary life stresses without resort to drugs show promise of preventive benefit, as it is well known that about 5% of the users of any comforting drug, whether it be alcohol, heroin, or amphetamine, go on to chronic misuse. The answers to the misuse problem are complex,

embracing social factors, drug availability, and individual psychopathology, and Dr. Bernstein's prescription for prompt family interviewing where adolescent drug use is suspected deserves the careful attention of all of us, as such action can be truly preventive.

Pregnancy: An Adolescent Crisis

MECKLENBURG* has focused on an urgent socio-medical problem in an emphatic manner. Rightly so, for as he has so graphically described, it is a major health problem and increasing. Reliance on parental guidance, church influence, elective education in the school system, and civic organizational efforts has proved inadequate. This is not meant to fault these efforts, for they have had some impact. A frequent comment from a concerned parent is "I tried, but (he or she) just won't listen to me anymore." This possibly is part of parental-sibling communication breakdown. However, an even more important factor is the normal adolescent drive for independence from parental influence.

Adolescent pregnancies are an important aspect of a broader area—adolescent health. This age group has health problems peculiar to it. Only recently has attention begun to be focused

on their health needs. Education provides only a part of the need. As the author points out, social factors contribute. Thus, an adequate approach must include a broad, continuing support program.

The problem justifies centralized planning, compulsory health education through all levels of the educational system, working in cooperation with, and part of, regional adolescent centers staffed with medical personnel, qualified to evaluate the emotional as well as the physical problems, psychologists, social counselors, clergy, employment counselors and legal advisors. Short term and long range guidance programs would be needed. Such a massive program would obviously need central control and administration and government funding. As the author states, appropriate governmental groups have not faced up to the need.

Morris S. Rothenem, M.D.
Minneapolis, Minnesota

Understanding Teenagers

THE TOPIC OF UNDERSTANDING teenagers has been fairly well exhausted by numerous authors. Yet the paper presented ably by Westman* testifies to our continued striving for answers regarding this perplexing period.

Westman's divisions of early, middle and late adolescence seem somewhat restrictive. With increasingly earlier onset of menarche many *early* adolescents are in the 11-12 year age level. And who can define where *late* adolescence ends? A fourth category of *post-adolescence* would deal with the individual whose need for continued education into the late twenties leaves him in limbo between adolescence and adulthood.

As Westman points out, the end of adolescence "may be deferred . . . until adult responsibilities

are formally assumed." But this period of deferral or waiting is filled with impersonal isolation, unproductivity, and often depression. Not contributing constructively to society for a prolonged period of time can lead an adolescent to assume the roles of critic and political activist. At least these activities bring a sense of doing something.

When "we are both afraid of and threatened by young people" the generation gap cries out for improved communications. How many of us feel fully comfortable speaking with teenagers, individually or in groups? But communicate with them we must. As Westman clearly summarizes, one day they will not only no longer need us, but will eagerly take our place. And then they will be adults and the process will begin again of understanding teenagers.

James G. Cardie, M.D.
Minneapolis, Minnesota

The Adolescent with Venereal Disease

DR. MAHAN's paper contains interesting and true points, and his suggestions are to be taken seriously. At the Teen-Age Medical Service we do not make a definite diagnosis of gonorrhea on a Gram stain of a penile discharge if there are mixed types of bacteria on the slide. But if the slide contains only intracellular diplococci, we can state that he probably has gonorrhea, and on this basis we treat him before the return of the culture. All of our males have cultures taken.

Serologies are drawn at four to six month intervals on sexually active males and females.

In working with adolescents, I want to alert physicians to the following:

1. Fifty percent of the population in the United States is under the age of 25. This group comprises an important part of society and a large segment of the patient population and is growing larger.
2. Physicians need to understand adolescent sexual behavior.
3. Physicians need to know about alternative

health care, such as mobile clinics, free clinics, contact centers for runaways, neighborhood youth centers, and the therapeutic counseling for drug abusers.

4. Physicians need to know the legislative status of the adolescent in Minnesota, as well as changes to this law which would prevent us from caring for the adolescent with our best medical judgment.

Physicians who are aware of these things should consider joining the Society for Adolescent Medicine. This includes all specialties if they work with youth. The Society for Adolescent Medicine has scheduled their meetings as follows:

<i>Spring</i>	<i>Fall</i>
1973—Los Angeles	1973—Chicago
1974—Cincinnati	1974—San Francisco
1975—Toronto	1975—Washington, D.C.

I urge you to learn more about how you can prepare adolescents and their parents to approach the problems in a sensible and mature fashion so that the dignity and respect of youth can be maintained, as well as the doctor-patient relationship.

Elizabeth Jerome, M.D.
Minneapolis, Minnesota

Cover Sculpture

"Nuclear Group"

The sculpture on this month's issue of MINNESOTA MEDICINE accompanies the Journal's theme of medicine and youth. The metallic figure grouping is by Dr. Dorothy Bernstein, a Minneapolis child and adolescent psychiatrist.

Sculpture, pottery, jewelry and graphics are media she has explored. She is past president of the American Psychiatric Art Association and in 1970 won the best of show award at the annual exhibit in San Francisco. At present her efforts are directed to establishing an active local chapter of this organization.

The photograph of the sculpture was done by Mark Bernstein, who is a third year student at the University of Minnesota Medical School.

Toxic Epidermal Necrolysis

(Scalded Skin Syndrome)

Associated with Staphylococci

TOXIC EPIDERMAL necrolysis is known in dermatology to occur in adults and children. The accumulation of more case reports; has suggested that this entity is not a definite disease but rather a clinical picture with multiple causations. On a visit to the Department of Dermatology at the University of Minnesota Lyell, himself, stated this view. In addition, to coagulase positive staphylococcus, various drugs and immunizations (tetanus, diphtheria, polio) have been associated with this condition. Also, cases have been reported where no definite cause could be identified.

In the paper by Saxena and Sethi* there were no fatalities. Unfortunately, this is not always the case. This entity may manifest itself as a rapidly progressive illness with a fatal outcome. It should be emphasized that therapy must take into consideration the possible cause. Supportive care

similar to that given to burn patients is indicated, as well as therapy directed at the causative agent, if known, (e.g. staphylococcus). The use of corticosteroids in those cases due to drugs has shortened the course. However, patients have recovered without the latter and their use would have to be tempered with the knowledge of the probable cause as well as the patient's condition.

In reading the clinical descriptions of the cases presented by Saxena and Sethi, one is reminded of a disease long known in pediatric literature—Dermatitis Exfoliativa Neotorum (Ritter's Disease). The latter has long been known to be caused/or associated with group 2 staphylococcus infection. Most authorities now agree that a differential between Ritter's Disease and toxic epidermal necrolysis, when caused by staphylococcus, cannot be made in an infant and may be identical.

Early Postpartum Insertion of Intrauterine Contraceptive Device

PATIENTS IN THOSE segments of the population who eschew the traditional postpartum examination and concomitantly the opportunity to avail themselves of the more effective means of contraception are the subject of continuing study around the world. Insertion of an intrauterine device prior to hospital dismissal attempts to utilize the acknowledged increased motivation for contraception by patients in the immediate postpartum period.

Several investigators have compared the complication rates of IUCD insertion within five days

of delivery to those of insertion at six or more weeks postpartum. Hemorrhage, infection, and perforation are not increased by early insertion. As confirmed by the report of Diamond and Freeman (in the January issue*), expulsion is the major disadvantage of early postpartum insertion of the commonly used devices.

Hopefully, more extensive studies will not show an increase in the low (4%) expulsion rate. Rashbaum and Wallach have reported for the petal IUCD which would seem to hold considerable promise as a device for puerperal insertion in the future.

Charles R. Fish, M.D.
Rochester, Minnesota

Are combination drug products useful in treatment involving concomitant use of two or more drugs?

Opinion & Dialogue

Doctor of Medicine

Louis Lasagna, M.D.
Professor and Chairman
Department of
Pharmacology & Toxicology
University of Rochester
School of Medicine
and Dentistry

Obviously, many drugs are given concomitantly. Whether it makes sense to combine medications in one preparation, be it capsule, tablet, or liquid, is a question that can be answered only by examining the advantages and disadvantages in the individual case.

Among the advantages is, first of all, convenience. The more medications that are taken concurrently and the more complicated the directions, the less likely the patient is to take medications accurately. From the standpoint of convenience and accuracy, and economy as well, you can make an important case for putting medications together in one preparation, as long as they are compatible.

By the same token, when you prescribe a properly tested and rational combination, you should have less worry about pharmaceutical or pharmacological compatibility — and about reasonable dosage ratios as well. Compatibility of the formulation should be demonstrated in the laboratory and clinic before the product is available for prescription—which is more than can usually be said for

the physician's own spontaneous creations. And, the dosage ratios employed in rational precompounded combinations are designed to meet the needs of substantial numbers of "typical" patients.

There is no doubt that many "atypical" patients are to be found, and for them the prefabricated combination must be rejected. But that hardly argues for eliminating rational combinations from the market. Think, for example, of the problems that would arise if the components of widely accepted combinations, like the oral contraceptives and the diuretic-antihypertensives, always had to be prescribed, purchased and ingested separately.

One disadvantage that comes to mind is some doctors' unawareness of the ingredients a given combination contains. For example, a doctor might know that a patient is allergic to aspirin but forget that a certain analgesic mixture, which he knows only by its trade name, contains aspirin. His prescription, then, causes considerable discomfort, to say the least. This problem is a function of physician education, rather than of combination therapy as such. Improving doctors' knowledge about all medicaments they prescribe is a problem that deserves tackling on its own.

Another accusation leveled at combination drugs is that they encourage sloppiness of diagnosis and treatment. In many cases, however, a combination may prove to be the most effective choice. A good ex-

ample of the usefulness of combinations appears in a recent article in the *Journal of Chronic Diseases* on the efficacy and side effects of an antihypertensive containing three ingredients, in which the track records of the combination drug and the individual ingredients were compared. Interestingly enough, whether the drugs were given individually or together, incidence and severity of side effects were the same. But blood pressure control was invariably better when the drugs were taken in one combination tablet than when they were taken separately (in "titratable" dosage) or in two or three different tablets.

Deciding which combinations constitute rational therapy obviously leads to a discussion of who is to determine which should be used and which should not. Realistically, I think combinations should be evaluated somewhat differently if they are old and established or new and untried.

In today's regulatory atmosphere, there is no possibility of a new combination being put on the market without a substantial amount of acceptable evidence in the form of controlled trials that show it to be safe and efficacious. On the other hand, I believe a different set of standards should apply to combination preparations that have been around for a long time. In other words, physician acceptance over a long period should be given some weight as evidence of the efficacy and safety of these drugs.

The FDA, however, does not seem to share this attitude. It often requires, for these older products, controlled trials that will monopolize the time of already overtired investiga-

tors and cost a great deal of money. I wish we could agree on a "grandfather clause" approach to preparations that have been in for a number of years, that have an apparently satisfactory track record.

For example, I think some of the antibiotic combinations that were taken off the market by the FDA performed quite well. I'm thinking particularly of penicillin-streptomycin combinations that patients—especially surgical patients—were given in injection. This made less discomfort for the patient, less demand on nurses' time, and fewer opportunities for dosing errors. To take such preparation off the market doesn't seem to be good medicine, unless actual usage showed a great deal of harm from the injections (rather than the preparation of the combination).

The point that should be emphasized is that there are both rational and irrational combinations. The real question is, who should determine which is which? Obviously, the FDA must play a major role in making this determination. In fact, I don't think it avoids taking the ultimate responsibility, but it should enlist the help of outside physicians and experts in assessing the evidence used in making the ultimate decision.

Maker of Medicine

V. Clarke Wescoe, M.D.
President
Vinthrop Laboratories

If two medications are used effectively to treat a certain condition, and it is known that they are compatible, it clearly is useful and convenient to provide them in one dosage form. It would make no sense, in fact, it would be pedantic, to insist they always be prescribed separately. To avoid the appearance of dandyism, the "expert" denies the combination because it is a fixed dosage form. When the "expert" invokes the concept of fixed dosage form he obscures the fact that single-ingredient pharmaceutical preparations are also fixed dosage forms. By a singular semantic exercise he implies a pejorative meaning to the term "fixed dose" only when he uses it with respect to combinations. What is ignored is the simple fact that only in the rarest of circumstances does any physician attempt to titrate an exact therapeutic response in his patient. It is quite possible that some aches and pains will respond to 500 mg. of aspirin yet that fact does not militate against the usual dose being 650 mg.

The other semantic ploy often called into play is to describe a combination product as rational or irrational.

Take antibiotic mixtures, the source of much of the criticism generated against

combinations generally. Obviously, no one should be exposed willy-nilly to the potential side effects of two or three antibiotics when only one is needed. At the same time there are cases where it is prudent to prescribe more than one. The clinician is the judge in these circumstances, as he should be.

There is no clear definition of the word rational. Most persons, I suppose, would find it synonymous with reasonable, but in many circumstances it may best be defined as the opinion of those in power at the moment.

Other factors govern combination therapy, not the least of which has been its broad use by practicing physicians anxious to achieve convenience in prescribing, to reduce medication error, and to save money for their patients. Combinations clearly have met the test on all three counts.

I have been impressed by studies showing that the rate of error climbs markedly with the number of medications to be taken, even with sophisticated patients. When medically justified, therefore, this factor alone supports the logic of combination therapy.

The cost argument for combinations appears to be irrefutable. In 1971, R. A. Gosselin studied the 71 combination products (excluding oral contraceptives) among the 200 most prescribed drugs. The study found that if all 71 products were discontinued, and if each ingredient in these combinations were prescribed separately, the price of medicines to patients would jump by \$443.2 million on a national basis! At a time when the cost of medical care is under so much fire, it would be nonsensical to boost costs without clearly irre-

futable medical reasons.

The part played by government on this question, of course, is fundamental. The FDA should play a role in determining which combinations are reasonable. That role, as defined by law and regulation, is to ensure that any medication on the market is safe and effective in line with its label claims. Certainly combinations are entitled to as much consideration as single entities—neither more nor less. So long as the addition of one drug to another does not make either less safe, or less effective, so long as they are compatible in a formulation, we have a reasonable product. It makes no sense to recommend the use of two products for certain conditions and to deny their being combined in a single form. An unhappy side effect of the problem concerns the efficacy panel discussions of many products submitted for review. The term "effective, but" has been freely interpreted to mean "ineffective" in toto, regardless of the merit of the individual drugs. This interpretation has placed numerous useful combination products in needless jeopardy.

In reading the actual reports of the review panels, it seems clear that some of the ratings were based less on scientific research and clinical observation than on the "informed" opinions of the panelists. These "informed" opinions were accepted at face value, while

the "informed" opinions of others who had used the products were rejected. All of this put combination products into a sort of scientific never-never land.

It should be kept in mind by all, government as well as others involved in our health care system, that advances in therapy are seldom made in leaps and bounds but rather by small painstaking steps—and that some of these steps have resulted from research in combination drugs as well as with single entities. Given the near-infinite biologic variation in patient response, this is hardly surprising to clinicians. It should not be to regulatory agencies either.

In the end, the practicing physician is in the best position to decide if a particular combination makes sense. Such a decision should not be made exclusively by those whose responsibility for continuing clinical care is limited. Clinicians are the best judges of efficacy because the ultimate proof of any product's effectiveness is acceptance by physicians who have observed its actions in patients over time. The corollary statement may be made about over-the-counter medicines, which would not long survive if they failed to afford the relief the user anticipates. That the antihistamine in a "cold" remedy may not *always* be necessary is no reason to proscribe the combination generally.

Opinion & Dialogue

What is your opinion, doctor?

We would welcome your comments.

The Pharmaceutical Manufacturers Association
1155 Fifteenth Street, N.W., Washington, D.C. 20005

MINOCIN® made the difference in just eight days.*

Clinical Data:

Patient: 47-year-old male.

Diagnosis: Severe pyoderma, left hand.

Culture: *Staphylococcus aureus*, coagulase positive and sensitive to MINOCIN.

Temperature: 102° F

Therapy: MINOCIN Minocycline HCl Capsules, 100 mg: 200 mg *stat*, 100 mg every 12 hours. Medication began 9/7/71. By fourth day, temperature was normal and pustular lesions considerably improved. Last dose taken 9/14/71.

Concomitant therapy: None.†

Semisynthetic

MINOCIN®
MINOCYCLINE HCl

Capsules, 100 mg: 2 *stat*, 1 q 12 h.

Indications: For the treatment of susceptible infections; e.g., *E. coli*, *D. pneumoniae*. For full list of approved indications consult labeling.

Contraindications: Hypersensitivity to any tetracycline.

Warnings: The use of tetracyclines during tooth development (last half of pregnancy, infancy and childhood to the age of 8 years) may cause permanent discoloration of the teeth (yellow-gray-brown). This is more common during long-term use but has been observed following repeated short-term courses. Enamel hypoplasia has also been reported. Tetracyclines, therefore, should not be used in this age group unless other drugs are not likely to be effective or are contraindicated. In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, use lower total doses, and, in prolonged therapy, determine serum levels. Photosensitivity manifested by an exaggerated sunburn reaction has also been observed in some individuals taking tetracyclines. Advise patients apt to be exposed to direct sunlight or ultraviolet light that such reaction can occur, and discontinue treatment at first evidence of skin erythema. Studies to date indicate that photosensitivity does not occur with MINOCIN Minocycline HCl. In patients with significantly impaired renal function, the antianabolic action of tetracycline may cause an increase in BUN, leading to azotemia, hyperphosphatemia, and acidosis. CNS side effects (lightheadedness, dizziness, vertigo) have been reported, may disappear during therapy, and always disappear rapidly when drug is discontinued. Caution patients who experience these symptoms about driving vehicles or using hazardous machinery while taking this drug.

Pregnancy: In animal studies, tetracyclines cross the placenta, are found in fetal tissues, and can have toxic effects on the developing fetus (often related to retardation of skeletal development). Embryotoxicity has been noted in animals treated early in pregnancy. Safety of use during human pregnancy has not been established. **Newborns, infants and children:** All tetracyclines form a stable calcium complex in any bone-forming tissue. Prematures, given oral doses of 25 mg/kg. every 6 hours, demonstrated a decrease

in fibula growth rate, reversible when drug was discontinued. Tetracyclines are present in the milk of lactating women who are taking a drug of this class.

Precautions: Use may result in overgrowth of nonsusceptible organisms, including fungi. If superinfection occurs, institute appropriate therapy. In venereal diseases when coexistent syphilis is suspected, darkfield examination should be done before treatment is started and blood serology repeated monthly for at least four months. Because tetracyclines have been shown to depress plasma prothrombin activity, patients on anticoagulant therapy may require downward adjustment of such dosage. Test for organ system dysfunction (e.g., renal, hepatic and hemopoietic) in long-term use. Treat all Group A beta hemolytic streptococcal infections for at least 10 days. Avoid giving tetracycline in conjunction with penicillin.

Adverse Reaction: GI: (with both oral and parenteral use): anorexia, nausea, vomiting, diarrhea, glossitis, dysphagia, enterocolitis, inflammatory lesions (with monilial overgrowth) in anogenital region. **Skin:** maculopapular and erythematous rashes. Exfoliative dermatitis (uncommon). Photosensitivity is discussed above ("Warnings"). **Renal toxicity:** rise in BUN, dose-related (see "Warnings"). **Hypersensitivity reactions:** urticaria, angioneurotic edema, anaphylaxis, anaphylactoid purpura, pericarditis, exacerbation of systemic lupus erythematosus. In young infants, bulging fontanels have been reported following full therapeutic dosage, disappearing rapidly when drug was discontinued. **Blood:** hemolytic anemia, thrombocytopenia, neutropenia, eosinophilia. **CNS:** (see "Warnings.") When given in high doses, tetracyclines may produce brown-black microscopic discoloration of thyroid glands; no abnormalities of thyroid function studies are known to occur.

NOTE: Concomitant therapy: Antacids containing aluminum, calcium, or magnesium impair absorption; do not give to patients taking oral minocycline. Studies to date indicate that absorption of MINOCIN is not notably influenced by foods and dairy products.

*Indicated in infections due to susceptible organisms. Culture and sensitivity testing recommended. Tetracyclines are not the drugs of choice in the treatment of any staphylococcal infection. †Case Report, Clinical Investigation Department, Lederle Laboratories.

LEDERLE LABORATORIES, A Division of American Cyanamid Company, Pearl River, New York 10965 12-20 436-2

Fracture Conference

A 19-Year-Old with Multiple Fractures

J. H. DOBYNS, M.D. AND G. E. SWANSON, M.D.

A 19-YEAR-OLD MALE WAS traveling in Europe prior to attending the University of Hamburg as an exchange student. As he was traveling with a professor and his wife through Finland, they stayed one night in rooms on the fifth floor of a hotel. After a dream, the patient awoke as he was crashing through a window to find himself falling five stories. Miraculously, there were no serious internal injuries and he was only unconscious for about 15 minutes. Figure 1-A is an Xray of his left hip, AP view, and no new information was added by the lateral. Figure 1-B is an

Doctors Dobyns and Swanson are in the Department of Orthopedics, Mayo Clinic, Rochester.

Fig. 1-B—The pelvic ring is disrupted at the left sacroiliac joint and wing of the ilium as well as at the right superior and inferior pubic rami.

Fig. 1-A—Comminuted subtrochanteric and intertrochanteric fracture, left hip.

Fig. 1-C—Minimally displaced fracture of the olecranon and radial head.

Fig. 2-A—Roentgenogram of left hip at six weeks post-injury. He has a full range of painless motion at the hip and $1\frac{3}{4}$ inch shortening.

Fig. 2-B—Six weeks postoperative roentgenogram, left elbow.

Fig. 3—Original AP and lateral roentgenograms of the right wrist. The distal carpal row including the distal pole of the scaphoid lies dorsal to the lunate and proximal scaphoid fragment.

Xray of the pelvis and Figure 1-C is of the left elbow. Dr. Cabanela, I wonder if you would tell us what you see on these Xrays and how you might manage the problem.

Dr. Cabanela:

I see a comminuted sub- and intertrochanteric fracture of the right femur. In addition, he has a right sacro-iliac disruption, pubic fractures of both the superior and inferior rami, and a fracture line through the wing of the ilium. We would prefer to treat his femoral fracture in traction. A modification of Russell's traction or even 90° - 90° traction (flexion of the hip and knee) would probably be adequate. Since he has pelvic injuries, skeletal traction with a tibial or distal femoral pin in a modified Russell's position would be better since his pelvic injuries should be treated with a pelvic sling.

There appears to be a fracture of the proximal ulna of his left elbow with each fragment containing 50% of the articular surface. There is a small fracture of the head of the radius, which is not displaced and should not require any further therapy. Once he is in good condition with his pelvic injuries, the fractured olecranon could be openly reduced and internally fixed with a tension wire as recommended by the AO group.

Dr. Swanson:

The pelvic and femoral fractures were treated with traction and a pelvic sling. The fracture of the olecranon was originally treated with a cancellous type of compression screw. Four days postoperatively the fracture fragments were separating and reduction was unsatisfactory. He was

returned to the operating room and a figure-eight tension wire was inserted. His femoral fracture at six and a half weeks after injury (Figure 2-A) demonstrates early union with massive callous present. We have done push-pull, abduction and adduction Xrays and cannot demonstrate any movement. He does have an inch and $\frac{3}{4}$ shortening of his femur on this side. Currently, he has a full range of painless motion of his hip and is on non-weight bearing crutch ambulation. Six and one half weeks after his injury the olecranon fracture is healing with a range of motion from 30° to 105° (Figure 2-B). At the time of his fall in

Fig. 4—Roentgenograms taken six weeks after open reduction and long-arm cast stabilization. The original deformity has recurred with increased ulnar translocation of the proximal carpal row.

Finland, he had this Xray of his right wrist, which demonstrates a trans-scaphoid, perilunate fracture-dislocation (Figure 3). The proximal pole of the scaphoid has stayed in relative alignment with the lunate and the lateral view reveals the capitate to be dorsal and out of its normal articulation with the lunate. The lunate is normally aligned with the distal articular surface of the radius. An open reduction through a dorsal incision was done in Finland shortly after his accident, and he was placed in a long-arm cast leaving his fingers free. On his return to the United States, the cast was removed and the Xray demonstrates the recurrence of the deformity (Figure 4).

Median nerve compression at the wrist is a frequent complication of this injury and on examination there was no sensation over the radial three digits of his hand. Thenar atrophy was present. The profile of his wrist at the time of surgery is seen in Figure 5. There is a volar prominence seen at the point of the hemostat which indicates the position of the volarly displaced lunate and scaphoid fragments. At the time of open reduction, the median nerve appears bruised and contused. As the flexor tendons and median nerve are pulled aside, the marked prominence of the proximal row of the carpus is visualized. There is a transverse tear through the volar radiocarpal ligament and volar subluxation of the proximal carpus (Figure 6). Following reduction of the lunate and proximal pole of the scaphoid, the tear in the volar capsule is noted to lie at the volar pole

Fig. 5—Volar prominence indicates the position of the displaced lunate-scaphoid fragment.

of the lunate. Dorsally, the pre-reduction configuration of the fragments is seen in Figure 7. Following reduction of the fragments, the scapholunate ligament is still intact in this instance because the line of force has been through the mid-carpus and then the scaphoid (Figure 8). After reduction and bone grafting of the scaphoid and some Kirschner wire stabilization, a dorsal, ligamentous reconstruction was done using one-half of the extensor carpi radialis longus tendon (Figure 9). It was

Fig. 6—Volar view of the carpus. The probe is in the tear of the volar carpal ligament. The displaced lunate is seen to bulge volarly, creating compression in the carpal tunnel. (A) displaced lunate; (B) distal capsule; (C) median nerve.

Fig. 8—Post-reduction dorsal view of the carpus. (A) The scapholunate ligament is intact; (B) Junction of the two scaphoid fragments.

attached to the dorsal aspect of the capitate, the scapholunate junction, and the distal portion of the radius. This will function as a reinforced capsular ligament so that with volar and dorsal flexion of the wrist, the possibilities of abnormal displacement will be reduced.

Post-reduction Xrays reveal the scaphoid fracture to be reduced and the radius, lunate, and capitate to be in normal alignment (Figure 10). There

Fig. 7—Dorsal view prior to reduction. (A) Volarly displaced lunate and proximal pole of the scaphoid; (B) Distal fragment of the scaphoid; (C) Capitate.

Fig. 9—Dorsal ligamentous reconstruction using one-half of the extensor carpi radialis longus tendon (A).

Fig. 10—Postoperative roentgenograms. Kirschner wires stabilize the scaphoid fracture as well as the perilunate dislocation.

Fig. 11—Wrist one year after open repair of trans-scaphoid perilunate dislocation.

is a fragment of bone seen dorsally on the lateral view that was from the triquetrum and is representative of the dorsal capsular stripping which was found. It was excised following this Xray.

This patient is only ten days postoperative, and we don't have any long-term follow-up to illustrate the expected course after the injury and surgery. Xrays from a patient who sustained an identical injury several years ago are presented. He also had complete median nerve paralysis distal to the wrist and was reduced through volar and dorsal approaches with similar reconstruction. Subsequent Xrays at six months show that his lunate did undergo partial avascular necrosis as well as the proximal pole of his scaphoid. At one year there is still a little bit of avascular necrosis of the proximal pole of the scaphoid but both bones are revascularizing (Figure 11). He had complete return of his median nerve with strong oppositional pinch and normal sensation. At this time, he had two-thirds of normal grip strength power and 60 to 70% of normal range of motion of his wrist.

Dr. O'Hara:

These dislocations are thought to be rather uncommon and MacAusland¹ states that in 24 years of orthopedic practice, he had seen only 27 cases. There are two types, depending upon whether the lunate retains its alignment with the distal radius or not. Type I is the perilunate dislocation in which the carpus dislocates dorsal to the lunate, with the lunate retaining its normal line with the distal radius. Type II is a pure lunate dislocation in which the lunate is squeezed volarly and lies perhaps in the carpal tunnel. Multiple fractures or dislocations of the scaphoid, capitate, triquetrum, radius or ulna can be associated with the basic perilunate dislocation and give a wide variety of x-ray appearances. Most authors feel that if these are seen within two weeks, closed reduction can be obtained with eventual good results. MacAusland recommends these be maintained in plaster for a period of four weeks with the wrist in 30 to 40° of flexion. If there is a trans-scaphoid fracture associated with the dislocation, Verdan² states that the plaster should be extended above the elbow because he was able to demonstrate motion at the scaphoid fracture site with pronation and supination of the forearm.

The indications for open treatment are not as clear. MacAusland gives four well-defined indications: (1) if closed reduction has not

been successful; (2) if there is severe injury to the carpal bones, usually capitate or scaphoid; (3) if the median nerve is compressed; and (4) if the injury is over two weeks old. Campbell et al.³ favor early open reduction if there is a trans-scaphoid or trans-capitate type of injury with multiple fragments of the capitate. They favor early open reduction and either removal or Kirschner wire fixation of the capitate fragment and early open reduction when there is a periscaphoid, perilunate dislocation with rotatory displacement of the scaphoid rather than a fracture.

When the dislocation is three to four weeks old, most authors feel that open reduction can still give us a good result if the articular surfaces are not severely damaged. Beyond five weeks, it is felt that severe soft tissue fibrosis and damage to the articular surfaces precludes a satisfactory result, even if anatomical reduction is obtained. Most people favor either partial or total arthrodesis of the wrist or excision of the proximal carpal row.

Dr. Dobyns:

We don't think such injuries are very rare, although the extreme examples that we see today are uncommon. Injuries to the wrist that result in some degree of instability are common. We feel that injuries obtained from dorsiflexion stresses are similar. How often do closed manipulative treatments take care of them adequately? I don't think anybody knows that for sure. We know the problems; we know when major subluxations recur; but the problems of minor instabilities that lead to later severe changes in the wrist are poorly discussed in the literature. Though there is an increasing concern with the need for open reduction, what should be done and how it should be done are vaguely described. The gross pathology as seen at surgery should assist in clarifying the requirements.

Dr. Paul Brand:

I haven't seen many of these cases in the acute stage in recent years, but we used to be concerned about the tendency of the capitate and lunate to make kind of a Z-shaped buckling. It is quite difficult to hold these bones in position while you are working with them. One may put the wrist in an odd position, like hyperflexion, to get the lunate in position, and then put the first Kirschner wire through the radius and nail the lunate; then reposition the wrist to a more neutral position and

pass the wire further into the capitate. In the postoperative phase this technique permits a more natural and neutral position. If you try to get your complete reduction initially without wires, you may find the wrist in a position which will interfere with rehabilitation when immobility is discontinued. By placing the wires in sequence one can often finish with good anatomical and physiological position of the wrist. This will help in the postoperative mobilization, prevent the pain at that stage, and obviate the need for later arthrodesis.

Dr. Dobyns:

Thank you, Doctor Brand. The technique you have described is a very useful one. I feel that we may have arrived at a mid-stage rather similar to ten years ago when more and more interest was devoted to the patterns of ligament rupture around the knee and the ankle. At that time we knew we had problems with those joints, but it wasn't too clear how many things could be injured, or how you needed to repair and replace them when they were injured. The wrist has been overlooked for many years and injuries are termed wrist sprain with little regard to the degree or site of the damage. The patterns of damage here probably are always multiple involving ligaments, bones, and joint surfaces. We have for many years known that the scapholunate ligament was disrupted in many of these injuries and some of us have tried to repair or replace that ligament. Discussion of the volar rent, what it meant, and what one should do about it has been almost minimal. Even those who said that one might preferably enter the wrist from the volar direction gave other reasons such as a need to relieve the pressure on the median nerve or to fish the lunate out of the tunnel. But there has been little said about this very big and very obvious deficiency in the structural integrity of the wrist. We are now at the point where we have information about the specific problems in each of these injuries and can specifically repair most of them. I am at the point where I look for reasons to open these major injuries (or even the minor ones for that matter), if the pattern of stability in the wrist is obviously not normal. The minor problems one sees are the scaphoid and lunate bones gradually spreading apart or the proximal row sinking down under the capitate; or, rarely, rising over the capitate. To repair many of these problems, particularly in the

19-YEAR-OLD WITH MULTIPLE FRACTURES

more severe injuries, an approach from both the volar and the dorsal aspects probably should be done at the same time. The reduction is much easier and it allows you to assess and repair liga-

mentous as well as bony structures about both surfaces of the wrist. Both tissues are important to eventual stability and good function.

- 7:00 dinner at the Radisson South
- 8:00 "GYNECOLOGICAL LUMPS AND BUMPS IN CHILDREN"—what not to do

This meeting will be held in the Methodist Hospital Auditorium, and there will be *no charge for attendance*. The meeting is open to all members of our medical community, whether or not they are affiliated with Methodist Hospital. There will be a charge for non-members of the Methodist Hospital Medical Staff who choose to attend the dinner program at Radisson South. AAFP will give eight hours of credit for attendance at this meeting.

The co-chairmen of this meeting are Dr. Edward Maeder, Jr. and Dr. Roy House, both of whom are associated with the St. Louis Park Medical Clinic. Their telephone number is 927-3123.

This world, where much is to be done and little to be known.—Samuel Johnson

Book Reviews

CALL THE DOCTOR: QUESTIONS PARENTS ASK ABOUT THEIR CHILDREN by Robert F. L. Polley, M.D. 164 pages. \$3.00. Parents Handbooks, 1971.

Baby and Child Care by Doctor Spock, the classic baby care book, and an excellent book in a light vein, *How to Raise Children at Home in Your Spare Time* by Doctor Marvin Gersh are now joined by another contribution for parents. However, this latter supposed aid does not measure up to the others in aid for the perplexed parent.

Areas well covered include skin care and bathing, thumb sucking, teething, infant food needs, and adoption. However, sections discussing breast feeding supplements, solid food and whole milk diet addition, self feeding, bottle propping, vitamin use, and an archaic view of tongue tie treatment are often contradictory to feelings of most teachers and experienced practitioners. A recurrent preoccupation with aid for stool elimination and explanation sections on colic are poor. Five pages on crib deaths will force most parents to sit at cribside every nap and sleep time. An area pertaining to teenage acne is out of place as are sections on drugs in our society, alcohol, and school problems which are not in the proper sphere of this book, although well done.

I found myself not knowing if the book was meant for the physician or for the parent. The continuity and subjects handled were far too broad—childhood and teenage cannot be covered in 164 pages! Sustained enjoyable reading or helpful answers are not part of this book. The two books noted earlier are musts—*Call the Doctor* is a must—not for the parent.

Lawrence J. Singher, M.D.
Minneapolis, Minnesota

REVIEW OF MEDICAL MICROBIOLOGY by Ernest Jawetz, Joseph L. Melnick, and Edward A. Adelberg. 10th Edition. Lange Medical Publications, Los Altos, California, 1972. 518 pp.

This book, as the title indicates, is a review of the topic of medical microbiology. The authors have oriented the presentation of the material to the physician, with emphasis on clinical infections and chemotherapy, with a significant portion of the volume also devoted to a discussion of the diagnosis of various infectious processes and to the principles of basic science. Dr. Jawetz, the senior author of this work, now in its tenth edition, is a figure of considerable stature in the fields of microbiology and clinical infectious diseases. The book demonstrates his combined training and experience.

The chapters are oriented to a review of basic princi-

ples through the first 160 pages, and the remaining pages are devoted to reviews of each of the numerous morphologically related organism categories. While the volume is meant to be a review, it is comprehensive in its scope, and fulfills the authors' objectives in an admirable manner. The narrative is readable with key words standing out in bold type. In attempting to be economical, however, the publishers have resorted to small print which taxes the reader settling down with the volume for any extended period of time. There is a free use of tables and diagrams and some actual photographs of material best illustrated in that manner. Reference listings are brief, and in general geared more for general reading in line with the "review" concept of the volume.

On the whole, the volume accomplishes its purpose, and, whereas at times one is not satisfied with the amount of information present, one must admit to truly receiving a rather comprehensive review of the field of medical microbiology through perusing its pages.

John M. Matsen, M.D.
Minneapolis, Minnesota

CONFESSIONS OF A GYNECOLOGIST, Anonymous, M.D. Doubleday and Company, Inc., Garden City, New York, 1972, 319 pages, \$7.95.

Behind the shield of anonymity, this author who, according to the publisher is a well known gynecologist, reminisces about his 30 years of practice. This allows him considerable leeway to comment on the foibles of patients as well as colleagues.

from natural childbirth to abortion and birth control. The style of the author is anecdotal. Narrative material is interspersed with factual information about current gynecological practice. In making interpretations beyond the cological practice. In making interpretations beyond the factual material, the doctor takes leeway. He does, however, admit that there is room for challenge of his opinions.

The author is especially effective in pointing out the gynecology patient who goes from doctor to doctor with vague complaints. He is less clear in effective management of such a patient.

In style and content, this book is directed to the general reader. The value to the doctor is in keeping up with what his patients may be reading. Women, who are the subject of this book, will be intrigued at what their gynecologist is thinking, but will also be piqued.

Dorothy M. Bernstein, M.D.

A name
worth repeating

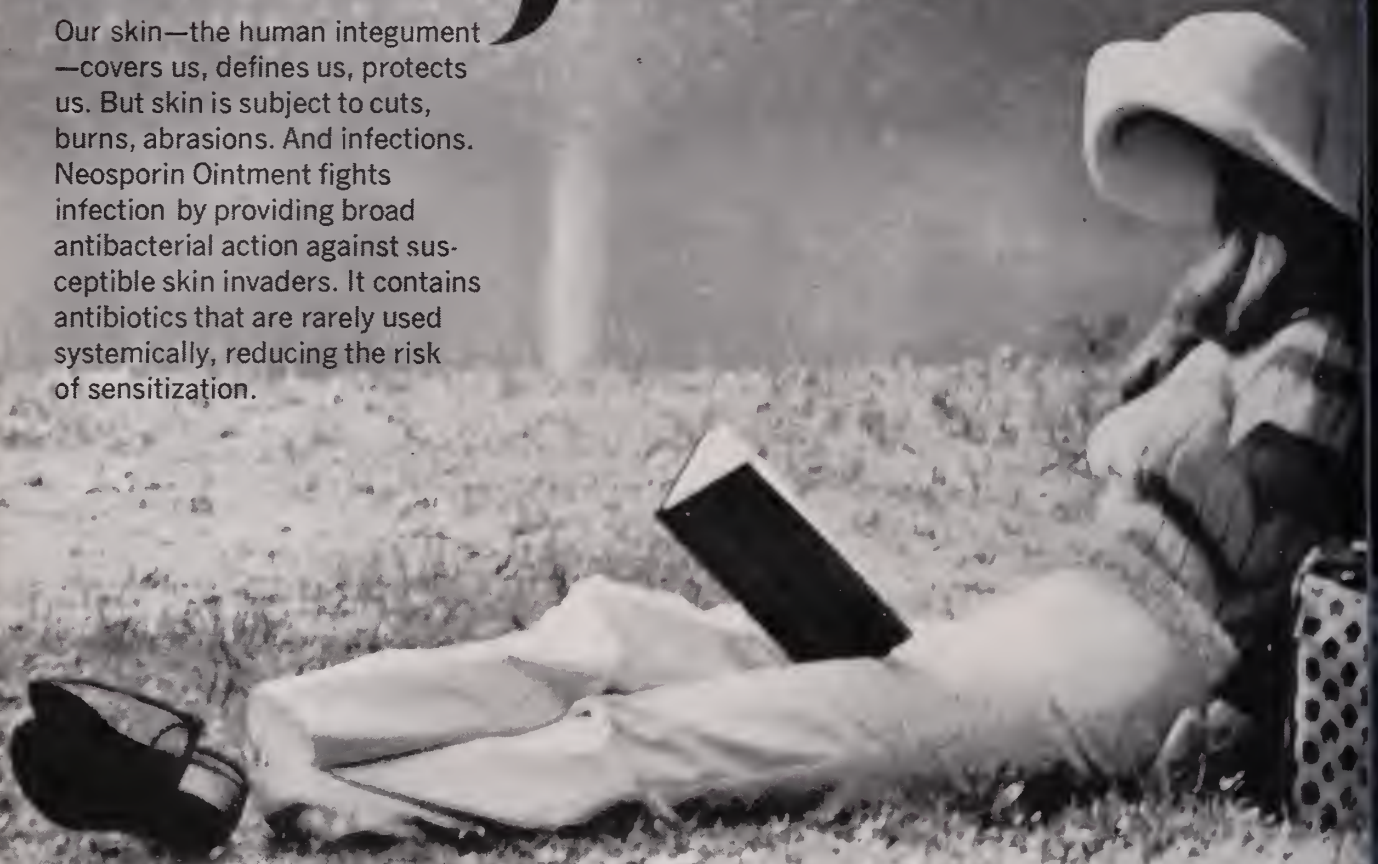

PANWARFIN[®]
sodium warfarin

2 mg. 2½ mg. 5 mg. 7½ mg. 10 mg. 25 mg.

Integument!

Our skin—the human integument—covers us, defines us, protects us. But skin is subject to cuts, burns, abrasions. And infections. Neosporin Ointment fights infection by providing broad antibacterial action against susceptible skin invaders. It contains antibiotics that are rarely used systemically, reducing the risk of sensitization.

INDICATIONS: *Therapeutically*, used as an adjunct to appropriate systemic therapy for topical infections, primary or secondary, due to susceptible organisms, as in: • infected burns, skin grafts, surgical incisions, otitis externa • primary pyodermas (impetigo, ecthyma, sycosis vulgaris, paronychia) • secondarily infected dermatoses (eczema, herpes, and seborrheic dermatitis) • traumatic lesions, inflamed or suppurating as a result of bacterial infection.

Prophylactically, the ointment may be used to prevent bacterial contamination in burns, skin grafts, incisions, and other clean lesions. For abrasions, minor cuts and wounds accidentally incurred, its use may prevent the development of infection and permit wound healing.

CONTRAINDICATIONS: Not for use in the external ear canal if the eardrum is perforated. This product is contraindicated in those individuals who have shown hypersensitivity to any of the components.

PRECAUTION: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.

Complete literature available on request from Professional Services Dept. PML.

NEOSPORIN[®] Ointment

(POLYMYXIN B-BACITRACIN-NEOMYCIN)

Each gram contains: Aerosporin[®] brand Polymyxin B Sulfate 5,000 units; zinc bacitracin 400 units; neomycin sulfate 5 mg (equivalent to 3.5 mg. neomycin base); special white petrolatum q.s. In tubes of 1 oz. and ½ oz. and ¼ oz. (approx.) foil pack

IN WINTER COUGHS

"For generations my family has insisted on Donnagel®-PG," says active young matron Mrs. T. Farnsworth Lipp (of the Upper Lipps), shown here with her charming son. "All the benefits of paregoric—without the unpleasant taste, don't you know? And Junior thinks Donnagel-PG tastes so much like bananas that I never worry about a slip between spoon and Lipp."

A Matter of Taste

With or without a silver spoon, a most tasteful solution in treating acute, non-specific diarrhea: all the benefits of paregoric, without the unpleasant taste. Donnagel®-PG treats accompanying cramping, tenesmus, and nausea as well as the diarrhea itself. Instead of unpleasant-tasting paregoric, it contains the therapeutic equivalent, powdered opium, to promote the production of formed stools and lessen the urge. And it provides the emulcent-detoxicant effects of kaolin and pectin, plus the antispasmodic benefits of elladonna alkaloids. And a good banana flavor to baby any taste.

Donnagel®-PG

Donnagel with paregoric equivalent

✓ Available on oral prescription or without prescription under limited circumstances as modified by applicable state law.

Each 30 cc. contains: Kaolin, 6.0 g.; Pectin, 142.8 mg.; Hyoscyamine sulfate, 0.1037 mg.; atropine sulfate, 0.0194 mg.; Hyoscine hydrobromide, 0.0065 mg.; Powdered opium, USP, 24.0 mg. (equivalent to paregoric 6 ml.) (Warning: may be habit forming); Sodium benzoate (preservative), 0.0 mg.; Alcohol, 5%. A.H. Robins Company, Richmond, Virginia 23220

A-H-ROBINS

CLEAR THE TRACT WITH THE ROBITUSSIN[®] LINE

The coughing season is here again. Time to rely on the four Robitussins and Cough Calmers to help clear the lower respiratory tract. All contain glyceryl guaiacolate, the efficient expectorant that works systemically to help increase the output of lower respiratory tract fluid. The enhanced flow of less viscid secretions soothes the tracheobronchial mucosa, promotes ciliary action, and makes thick, inspissated mucus less viscid and easier to raise. Available on your prescription or recommendation.

For coughs of colds and "flu"

ROBITUSSIN[®]

Each 5 cc. contains:

Glyceryl guaiacolate 100 mg.
 Alcohol, 3.5%

For unproductive allergic coughs

ROBITUSSIN A-C[®]

Each 5 cc. contains:

Glyceryl guaiacolate 100 mg.
 Pheniramine maleate 7.5 mg.
 Codeine phosphate 10.0 mg.
 (warning: may be habit forming)
 Alcohol, 3.5%

Non-narcotic for 6-8 hr. cough control

ROBITUSSIN-DM[®]

Each 5 cc. contains:

Glyceryl guaiacolate 100 mg.
 Dextromethorphan hydrobromide 15 mg.
 Alcohol, 1.4%

Robitussin-DM in solid form for "coughs on the go"

COUGH CALMERS[®]

Each Cough Calmer contains:

Glyceryl guaiacolate 50 mg.
 Dextromethorphan hydrobromide 7.5 mg.

Relieves cough, clears sinuses and nasal passages—keeps them "drip-dry" but not bone dry

ROBITUSSIN-PE[®]

Each 5 cc. contains:

Glyceryl guaiacolate 100 mg.
 Phenylephrine hydrochloride 10 mg.
 Alcohol, 1.4%

Select the Robitussin[®]
 "ear-Tract" Formulation
 that Treats Your Patient's

WAYZATA MEDICAL BUILDING OFFICE SUITES—Located in the fastest growing suburban area in the Twin Cities. We offer:

- Surrounding area of lakes, country clubs, woods, beautiful homes;
- Unsurpassed medical building facilities
- Fast growing area—high median family incomes
- Beautiful building—inside and out
- Inner courtyard with trees and landscaping
- Heated indoor parking
- Adjacent access to freeway system
- Low rental rates—favorable base terms
- Financial services

We have grown to fourteen specialties since our building was completed two years ago. We particularly are interested in Orthopedics, Psychiatry, Urology, Otolaryngology, Internal Medicine and Dentistry. Give us a call. We have a lot more to show you and to talk about. Reply to: Mr. Paske, Wayzata Medical Building, 250 North Central Avenue, Wayzata, Minn. 55391, (612) 473-0031.

WANTED: PHYSICIAN, WISHEK, NORTH DAKOTA—Wishek population—1400 plus 5000 surrounding area. 32 bed modern Hospital, 87 bed new Nursing Home. Hospital Board owns new \$35,000.00 home to be given to Physician rent free for 6 months; thereafter, reasonable rent. Free Clinic for 6 months; thereafter, rent reasonable. Hospital Board owns all Clinic equipment and instruments plus Xray Machine. Present Physician left Wishek to finish Surgical Residency. New 12 grade Public School System open Fall, 1972. Wishek is located in south central North Dakota. City Civic Center Auditorium. Green Lake is 12 miles from Wishek for good fishing, boating and lake lots. City outdoor heated Swimming Pool with tennis courts. Modern Park Facilities. 9-hole Golf Course with Club House. For further information contact: Eugene Wiest, Mayor, Wishek, North Dakota, Telephone 452-2255.

GENERAL PRACTITIONER needed as associate in county seat community of 2,000. Modern 35 bed hospital! 4 blocks from fully equipped clinic. An excellent opportunity to live the good life in rural Minnesota. Write: Minnesota Medicine-477, 375 Jackson St., St. Paul 55101.

WANTED—Family physician to join two family physicians, a Board certified Internist, an Obstetrician—Gynecologist and Surgeon in well established clinic. Early partnership. Excellent hospital facilities, churches, schools etc. Call 612-425-2117 collect or write Osseo Clinic, Osseo, Minnesota 55369.

DOCTOR: Will "sit" your office while you school or vacation. Monday through Saturday. No OB, night calls, hospital patients or emergency. Must be within commuting distance of Twin Cities. J. E. Douglass, M.D. 612-455-7861. 2050 Delaware, West St. Paul, Minn. 55118.

INTERNIST wanted to join three other Internists in Department of Internal Medicine in twenty man multispecialty group, including sizeable Department of Family Medicine. \$30,000.00 to start, partnership in two years, many fringe benefits, new clinic, new hospital to be started soon, city of 25,000 with clean air, no traffic problems, no street crime. Call or write H. P. Van Cleve, M.D., Austin Clinic, Austin, Minnesota 55912 (Telephone (507) 433-7351)

ASSOCIATE FOR AAFP member in professional corporation or expense and call sharing association. New clinic building in construction to serve three rural communities. Immediate partnership in corporation, if desired. All corporate benefits immediately. Located in beautiful Hiawatha Valley of southeastern Minnesota, 35 miles from Mayo Clinic and 55 miles from Gunderson Clinic. Contact R. L. Sauer, M.D., Root River Valley Medical Clinic LTD., Box 496, Preston, Minnesota 55965.

ASSOCIATES WANTED: Family doctors to join a growing Family Practice Department in a large multiple specialty medical center, Minneapolis suburb. Excellent opportunity for teaching undergraduate and graduate students in Family Practice. Four man department with excellent growth potential. Reply to Dr. Harley J. Racer, Chairman Family Practice Department, St. Louis Park Medical Center, St. Louis Park, MN 55416. Telephone 612-927-3320.

FAMILY PRACTITIONER for rural area as member of 22 man multispecialty medical and surgical group. Opportunity for rural practice which incorporates advantages of membership in an urban medical group. Includes: *Educational programs:* Conferences, paid medical meetings, hospital rotations, peer review and support; *Quality Medical Care:* Ease of consultation, excellent lab and X-ray, regular call schedule and time off; *Economic Benefits:* Adequate salary, year end bonus, pension plan, group disability, life insurance. Write 210 Ninth Street S.E., Rochester, Minnesota; or phone collect, J. J. Garber, M.D., 507-288-3443.

WANTED—INTERNIST: Bd. Qual.; For two Internists and two Surgeons group in Iowa; own building; large modern hospital; Midwest shopping and medical center; 30,000; well balanced economy; 2 hours to three large cities; lake resort 10 miles away; hunting and fishing area; skiing 2 hours away; excellent school system; Junior College; art gallery, superb library facilities. Salary (\$35,000-\$40,000) depending on qualifications. Early partnership. Write Minnesota Medicine-476, 375 Jackson, St., St. Paul 55101.

Integrated Psychiatry and Its Practical Application

In A 273 Bed General Hospital

IRVING C. BERNSTEIN, M.D. M.S.

THE PRIVATE HOSPITAL care of psychiatric patients in Minneapolis has been constantly changing and progressing during the past two decades. In 1951 only one private hospital providing complete psychiatric care existed in Minneapolis, which was the 60-bed suburban Glenwood Hills Psychiatric Hospital, a hospital isolated from the general practice of medicine. It has since become a general hospital, with a separate building for psychiatric patients. The establishment of psychiatry in general hospitals began with the opening of the Fairview Hospital Psychiatric Unit in 1955. Shortly afterward, St. Mary's Hospital opened a psychiatric ward, and then a number of units were opened at Abbott, St. Barnabas, Northwestern, and North Memorial hospitals, each with individual orientation, but all centered in a wing or section of the respective general hospital.

The acceptance of these units was a gratifying experience, and psychiatrists began to be accepted as "real doctors." The staff of the obstetrical and gynecological service at the University of Minnesota Hospital was managing the majority of the psychiatric illnesses occurring in their patients effectively and efficiently on the ward, and the acceptance of psychiatry and psychiatrists was the greatest there. The psychiatrist involved in this endeavor had a joint teaching appointment in psychiatry and obstetrics and gynecology, an early example of integrated psychiatry.¹

In 1969 Mt. Sinai Hospital decided to have a psychiatric service, an integrated unit. It would not only be less expensive to open (Mt. Sinai already had four security rooms) but it might be better for all the patients, and provide an opportunity to stimulate, support, and educate all hospital personnel in dealing with the emotional aspects of illness. The service was to be based on

the philosophy that the needs of most psychiatric patients can best be treated on general medical wards which would produce mutual benefit to psychiatric and medical-surgical patients.

Mt. Sinai already had a Methadone program functioning under the direction of an internist; however, Model City administrators who provided the funds for this program stipulated that they would continue to support it only if it was under the direction of a psychiatrist and had a functioning rehabilitation section. Thus, the opportunity presented to establish the essentials of a mental hygiene clinic with in-patient psychiatric care, out-patient psychiatric care, emergency care, partial hospitalization, and education and consultation. Furthermore, it gave the Chief of Psychiatry at Mt. Sinai Hospital the immediate opportunity to work with both the administration of the hospital and a consumer organization.

To study the problem in detail, Greenwich Hospital in Connecticut was visited. This hospital has had an integrated psychiatric service since the late 1940's, its development had been reported by Dale and Wright in 1962.^{2,3} Awareness of this unit gave the initial workers more impetus and enthusiasm to set up a similar unit at Mt. Sinai. An executive committee of three psychiatrists was appointed to establish tentative policies for the unit. Some of the by-laws at Mt. Sinai Hospital had to be changed to accommodate psychiatry, including one stating that "the hospital is not able to assume the responsibility for the care and supervision of disturbed or dangerous patients on an open station."

It was agreed that any attending physician could transfer or admit a patient to a security room without first having the approval of a psychiatrist. The goal always in mind was to develop psychiatric expertise in all physicians. The Chief of Psychiatry became a member of the Executive Committee within the first year of operation.

¹Presented at Midwinter Meeting of the Colorado Psychiatric Society, Vail, Colorado January 1972.

Dr. Bernstein is a Clinical Professor, Psychiatry, Obstetrics & Gynecology, University of Minnesota Medical School; Chief of Psychiatry, Mt. Sinai Hospital, Minneapolis, Minnesota.

The first psychiatric patient on the new program was admitted to Mt. Sinai hospital on May 15, 1971, only 45 days after the target date set one year earlier. On that day, in Minneapolis, psychiatry returned to the confines of general medicine, where it belongs, after being isolated for years in its "Ivory Tower" or in a State Hospital, or in Glenwood Hills Hospital. Education has been considered as a primary goal of the integrated service from its inception and has included the medical students and house staff. Students on their Mt. Sinai medical experience are given a weekly seminar. Some students chose an elective with a staff psychiatrist either full or halftime for three or six weeks. Some of the Minneapolis nursing schools, including the University of Minnesota, are now sending their students to Mt. Sinai hospital for psychiatric experience.

The only criteria for admission to the psychiatric service is that the patient's behavior be such that the patient can be treated at Mt. Sinai. The usual categories of psychiatric patients have been treated (Table 1, 2, 3). Patients are admitted to any empty bed in the hospital. Electroshock therapy (E.S.T.) is administered in the patient's room, including double rooms and four bed rooms, after the curtain is drawn. The effectiveness of E.S.T. in correctly chosen patients and the smoothness of its administration have been a surprise to many

of the doctors and other staff members at Mt. Sinai. Of 120 psychiatric admissions in the first seven months, 24 received E.S.T. (Table 4). In the first seven months of operation, only three patients have been transferred to another hospital in the city and no patient has been committed to a State Hospital. One transfer occurred soon after the unit opened and probably would not be transferred today since psychiatric patients are now more accepted by the Mt. Sinai Medical Staff.

It is obvious that hospitals can function without a psychiatric service, but can they function better with such a service? After seven months' experience, the staff and administration at Mt. Sinai would agree that psychiatry has assisted the hospital to function better and that all their patients are receiving better care and even that lives are being saved. One example was a 95-year-old patient with anorexia nervosa who was about to die and whose life was saved by E.S.T.⁴ The staff has been particularly impressed with psychiatry's effectiveness in managing masked, as well as obvious, depressions, manic-depressive episodes, and behavior problems. All staff members are constantly being advised and shown that treating all patients with dignity and using simple techniques such as calling adult patients by Mr., Mrs., or Miss, will contribute to improved behavior by giving these patients a "corrective emotional ex-

perience."⁵ Some resistance was encountered and handled when these and similar changes were first advocated.

The positive feelings being shown toward psychiatry by the medical staff now were not so evident in our planning and early days. At that

time most of the staff felt psychiatric patients should be segregated, feelings based on the staff's fears without an understanding of the psychiatric problems involved. To combat these feelings the referring physician is encouraged to participate in the examination and treatment of the psychiatric

cases they admit to the hospital. They can then observe how a psychiatrist functions and that he functions not unlike the usual physician, making a diagnosis, instituting treatment and making a disposition. The psychiatrist choosing to practice in an integrated general hospital will have to practice this way. He must be a medical doctor in the strictest sense of the word. In many instances, the patient is not transferred to the psychiatrist's service, and the psychiatrist acts only as an adviser. This is in keeping with the philosophy of the service, which is to foster psychiatric understanding by all physicians and to encourage the family physician or surgeon to assume responsibility for most of the emotional care of his patients, using the psychiatrist only when specifically needed. This gives all patients better care and especially psychiatric patients, who are then not isolated from familiar surroundings and their own physicians. If the case is primarily a psychiatric problem, the patient is transferred to the psychiatrist's service, with the referring doctor being the adviser. This procedure has worked smoothly. Patients with emotional problems are not staying in the hospital as long as they did in the past, the average length of stay for psychiatric patients being only 11.4 days (Table 4).

TABLE 4
Summary First Seven Months
Mount Sinai Psychiatric Service

	Total First 7 Months			Received EST
	Male	Female	Total	
Psychoses	8	17	25	9
Neuroses	9	43	52	15
Personality Disorders	5	38	43	0
	22	98	120	24

Total Psychiatric Days = 1,378

Average Length of Stay = 11.4

In general, the integrated psychiatric service at Mt. Sinai has gone smoothly, though there have been problems—some medical, some administrative—but these were expected and are handled as they occur. Examples of such problems are:

1. One doctor's patient with a "coronary" was disturbed by a noisy psychiatric patient in the next room. Since the doctor refused to move

his patient, the psychiatric patient was transferred to a psychiatric ward of another hospital. This type of situation would probably not occur today because the psychiatric patient is more acceptable at Mt. Sinai by the staff.

2. Early, some of the doctors felt that their "normal" patients should not be in rooms with "psychiatric" patients, but when some of these "normal" patients developed psychiatric symptoms the doctors ceased complaining.
3. An otologist complained of a noisy child being on the pediatric ward. He wondered whether such a "psychiatric" patient should be treated with the usual pediatric patient. This "noisy" child had a subarachnoid hemorrhage and it was demonstrated to him that a quiet child might be more emotionally ill than a noisy child.
4. Some members of the Hospital Board were concerned about the "image" of the hospital having an integrated psychiatric unit. They were pleased when the newspaper reports were uniformly favorable.

How the Medical Staff's negative feelings about psychiatry have been handled have already been stated. To combat the negative feelings of others, educational lectures by the psychiatric staff are being given and are beginning to counteract these feelings.

In summary, the psychiatric service at Mt. Sinai hospital is now seven months old, and it appears that it is here to stay. Patients are receiving excellent care, the medical staff and administrative staff are pleased and cooperating, the psychiatry service is flourishing, two part-time psychologists are busy, the occupational therapy department is growing, social service is effective, and supportive group therapy started recently. More integration, especially in pediatrics, better out-patient follow-up, and the obtaining of improved interviewing rooms have top priority for the immediate future.

This kind of psychiatric facility can be recommended, because it will provide excellent care for psychiatric patients; it will improve medical care throughout the hospital, and it will advance psychiatric teaching, providing there is a dedicated psychiatric staff, a cooperative hospital administration, a receptive medical staff, and a willing nursing service.

In Memoriam

The buried are not lost, but gone before.—Ebenezer Elliott.

DUNCAN M. MASSON, M.D.

Dr. D. Morrison Masson, 80, emeritus member of the Mayo Clinic staff, died December 14, after a long illness. He was a specialist in internal medicine at the Mayo Clinic from 1922 until he retired in 1957.

Dr. Masson was born in Owen Sound, Ontario, Canada and received his medical education at the University of Toronto. In 1921 he came to Rochester to begin a fellowship in surgery and the following year was appointed first assistant in medicine. In 1925 he was appointed to the staff and in 1936 became an assistant professor in the Mayo Graduate School.

He was a member of the American Medical Association and the Zumbro Valley Medical Society and an Associate and 50 Club Member of the Minnesota State Medical Association.

Dr. Masson is survived by his wife, Laura May, a son, D. Morrison Masson, Jr. and two daughters, May and Jean.

DAVID J. HALPERN, M.D.

Dr. David Halpern, 65, Brewster physician, died September 26, following a heart attack. He came to Brewster in 1932 and served on the staff of the Worthington Regional Hospital for the past 40 years.

Dr. Halpern was a member of the Southwestern Minnesota Medical Society, the American Medical Association and the Minnesota State Medical Association. His medical degree was obtained at the University of Minnesota Medical School.

He is survived by his wife, Maude.

W. R. KOONS, M.D.

Dr. W. Koons, 51, Mahanomen physician, was killed October 7, when the automobile he was driving went out of control, left the road and overturned into a shallow pond.

Born in Washington, D.C., Dr. Koons graduated from Northwestern Medical School in Chicago in 1951. He practiced in Lidgerwood, North Dakota, from 1952-1957 and later came to Mahanomen to practice.

He was a member of the Minnesota State Medical Association, the Clay-Becker County Medical Society, the American Medical Association and the Academy of General Practitioners.

Dr. Koons is survived by his wife, Herdes, and four daughters, Andrea, Valerie, Kimberly and Stacy.

ARTHUR M. MULLIGAN, M.D.

Dr. Arthur M. Mulligan, 69, Brainerd physician, died October 23. He had resided in Brainerd since 1936 and was a member of the Upper Mississippi Medical Society, the American Medical Association and the Minnesota State Medical Association.

Dr. Mulligan was born in Beatrice, Nebraska, and attended the University of Nebraska College of Medicine.

He is survived by his wife, Mildred, two sons, Mike and Pat, and two daughters, Zita and Patricia.

ROBERT J. NORDBERG, M.D.

Dr. Robert Nordberg, 29, Little Falls physician, died November 6. He had suffered a severe electrical shock at his home in July.

Dr. Nordberg was born in Little Falls and had graduated from the University of Minnesota Medical School in 1967.

He is survived by his wife, Janice and three daughters, Cynthia, Julie and Brenda.

FREDRICK A. WILLIUS, M.D.

Dr. Fredrick A. Willius, Mayo Clinic emeritus cardiologist, died October 19 at the age of 83. Born in St. Paul, Dr. Willius received his medical degree from the University of Minnesota Medical School in 1914. He became a fellow in surgery in 1915, joined the Clinic staff as a consultant in medicine in 1920 and became a senior consultant in 1945.

Dr. Willius was certified as a specialist in internal medicine by the American Board of Internal Medicine, was a fellow in the American College of Physicians, former president of the Minnesota Society for the Study of Diseases of the Heart and Circulation, authored many books, was a member of the Zumbro Valley Medical Society and the American Medical Association and an Associate and 50 Club Member of the Minnesota State Medical Association.

He is survived by his wife, Stella, and three daughters, Mary Elizabeth, Jane Eleanor and Dorothy.

ERLING W. HANSEN, M.D.

Dr. Erling W. Hansen, 82, Minneapolis otolaryngologist, died December 17. He received his medical degree from the University of Minnesota Medical School in 1915, and was a member of the American Medical Association and the Hennepin County Medical Society. He was also a Life Member and 50 Club Member of the Minnesota State Medical Association.

Dr. Hansen is survived by his wife, Anna Ruth, son, Gordon, and daughter, Mary.

ALBERT T. HAYS, M.D.

Dr. Albert T. Hays, 65, Minneapolis surgeon, died November 6. He was born in St. Paul, and attended the University of Minnesota Medical School.

Dr. Hays was a member of the Hennepin County Medical Society, the American Medical Association and the Minnesota State Medical Association.

He is survived by his wife, Genevieve, son, Thomas, and two daughters, Ann and Mary.

Acute Viral Hepatitis

Patients with acute viral hepatitis occasionally deteriorate rapidly with a so-called fulminant form of the disease. The mortality rate in this situation is at least 80% despite all known forms of therapy. There is now the possibility that treatment with specific antibody to Australia antigen or serum hepatitis-associated antigen (HbAg) may permit survival. Supplies of antibody are limited and its usefulness has not yet been claimed by uncontrolled observations. The National Blood Resource Branch of the National Heart and Lung Institute has initiated a controlled multi-center study to assess the efficacy of such therapy. Dangers associated with the use of antibody therapy, while conceivable, have not been recognized to date.

The Mayo Clinic is participating in this study and is prepared to receive patients with this condition and enter them into the study if they meet certain criteria and provide full consent. A member of the Liver Group at 1-507-282-2511 will be pleased to discuss any patient.

Drug Abuse

Everybody experiences psychic tension.

Most people can handle this tension.

Some people develop excessive psychic tension and need your counseling

and a few may need counseling
and the psychotropic action of Valium® (diazepam).

Before deciding to make Valium (diazepam) part of your treatment plan, check on whether or not the patient is presently taking drugs and, if so, what his response has been. Along with the medical and social history, this information can help you determine initial dosage, the possibility of side effects and the ultimate prospects of success or failure.

While Valium can be a most helpful adjunct to your counseling, it should be prescribed only as long as excessive psychic tension persists and should be discontinued when you decide it has accomplished its therapeutic task. In general, when dosage guidelines are followed, Valium is well tolerated (see Dosage). For convenience it is available in 2-mg, 5-mg and 10-mg tablets.

Drowsiness, fatigue and ataxia have been the most commonly reported side effects.

Until response is determined, patients receiving Valium should be cautioned against engaging in hazardous occupations requiring complete mental alertness, such as driving or operating machinery.

Roche Laboratories
Division of Hoffmann-La Roche Inc.
Nutley, N.J. 07110

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect.

Adults: Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 100 and 500. All strengths also available in Tel-E-Dose® packages of 1000.

Change the AMA!

Maybe you're one of those doctors at odds with some AMA policies. Your question is: how do you change them?

First, consider who sets those policies. In a real sense, it is you. You elect the delegates to your state association. They in turn elect the delegates who will represent your views in the AMA House.

As an active, involved member, you can influence policy by making your views known to your delegates, both national and state. It is your democratic right — and responsibility.

Write your delegates, call them, see them. If they aren't responsive, tell them they'll be hearing from you at election time.

You can also go directly to the top and express your views before the AMA House's Reference Committees at either of the two annual conventions.

But it's up to you. If you have strong convictions about something that should be changed, you can be heard.

Join us. We are only what the doctors of this country want us to be. Find out more about the AMA. Send for the pamphlet, "The AMA and the American Doctor: Sharing a Common Goal." Write: Dept. DW, at the address below.

JOIN US. WE CAN DO MUCH MORE TOGETHER.

acute arthritic inflammation...heat that freezes

In acute rheumatoid arthritis consider Tandearil. The anti-inflammatory action of Tandearil quickly helps reduce heat, pain, swelling, and stiffness. Results are usually seen in 3 or 4 days. Try it for a week when the symptoms defy aspirin control.

Remember that Tandearil is not a simple analgesic. It should not be used on patients responding to routine therapy. Before using, please read the prescribing information. It's summarized below.

Tandearil® helps take the heat off oxyphenbutazone NF Geigy

Tablets of 100 mg.

Important Note: This drug is not a simple analgesic. Do not administer casually. Carefully evaluate patients before starting treatment and keep them under close supervision. Obtain a detailed history, and complete physical and laboratory examination (complete hemogram, urinalysis, etc.) before prescribing and at frequent intervals thereafter. Carefully select patients, avoiding those responsive to routine measures, contraindicated patients or those who cannot be observed frequently. Warn patients not to exceed recommended dosage. Short-term relief of severe symptoms with the smallest possible dosage is the goal of therapy. Dosage should be taken with meals or a full glass of milk. Patients should discontinue the drug and report immediately any sign of: fever, sore throat, oral lesions (symptoms of blood dyscrasias); dyspepsia, epigastric pain, symptoms of anemia, black or tarry stools or other evidence of intestinal ulceration or hemorrhage, skin reactions, significant weight gain or edema. A one-week trial period is adequate. Discontinue in the absence of a favorable response. Restrict treatment periods to one week in patients over sixty.

Indications: Acute gouty arthritis, rheumatoid arthritis, rheumatoid spondylitis.

Contraindications: Children 14 years or less; senile patients; history or symptoms of G.I. inflammation or ulceration including severe, recurrent or persistent dyspepsia; history or presence of drug allergy; blood dyscrasias; renal, hepatic or cardiac dysfunction; hypertension; thyroid disease; systemic edema; stomatitis and salivary gland enlargement due to the drug; polymyalgia rheumatica and temporal arteritis; patients receiving other potent chemotherapeutic agents, or long-term anti-coagulant therapy.

Warnings: Age, weight, dosage, duration of therapy, existence of concomitant diseases, and concurrent potent chemotherapy affect incidence of toxic reactions. Carefully instruct and observe the individual patient, especially the aging (forty years and over) who have increased susceptibility to the toxicity of the drug. Use lowest effective dosage. Weigh initially unpredictable benefits against po-

tential risk of severe, even fatal, reactions. The disease condition itself is unaltered by the drug. Use with caution in first trimester of pregnancy and in nursing mothers. Drug may appear in cord blood and breast milk. Serious, even fatal, blood dyscrasias, including aplastic anemia, may occur suddenly despite regular hemograms, and may become manifest days or weeks after cessation of drug. Any significant change in total white count, relative decrease in granulocytes, appearance of immature forms, or fall in hematocrit should signal immediate cessation of therapy and complete hematologic investigation. Unexplained bleeding involving CNS, adrenals, and G.I. tract has occurred. The drug may potentiate action of insulin, sulfonamides, and sulfonamide-type agents. Carefully observe patients taking these agents. Nontoxic and toxic goiters and myxedema have been reported (the drug reduces iodine uptake by the thyroid). Blurred vision can be a significant toxic symptom worthy of a complete ophthalmological examination. Swelling of ankles or face in patients under sixty may be prevented by reducing dosage. If edema occurs in patients over sixty, discontinue drug.

Precautions: The following should be accomplished at regular intervals: Careful detailed history for disease being treated and detection of earliest signs of adverse reactions; complete physical examination including check of patient's weight; complete weekly (especially for the aging) or an every two week blood check; pertinent laboratory studies. Caution patients about participating in activity requiring alertness and coordination, as driving a car, etc. Cases of leukemia have been reported in patients with a history of short- and long-term therapy. The majority of these patients were over forty. Remember that arthritic-type pains can be the presenting symptom of leukemia.

Adverse Reactions: This is a potent drug; its misuse can lead to serious results. Review detailed information before beginning therapy. Ulcerative esophagitis, acute and reactivated gastric and duodenal ulcer with perforation and hemorrhage, ulceration and perforation of large bowel, occult G.I. bleeding with anemia,

gastritis, epigastric pain, hematemesis, dyspepsia, nausea, vomiting and diarrhea, abdominal distention, agranulocytosis, epistaxis, anemia, hemolytic anemia, anemia due to blood loss including occult G.I. bleeding, thrombocytopenia, pancytopenia, leukemia, leukopenia, bone marrow depression, sodium and chloride retention, water retention and edema, plasma dilution, respiratory alkalosis, metabolic acidosis, fetal and nonfetal hepatitis (cholestasis may or may not be prominent), petechiae, purpura without thrombocytopenia, toxic pruritus, erythema nodosum, erythema multiforme, Stevens-Johnson syndrome, Lyell's syndrome (toxic necrotizing epidermolysis), exfoliative dermatitis, serum sickness, hypersensitivity angitis (polyarteritis), anaphylactic shock, urticaria, arthralgia, fever, rashes (all allergic reactions require prompt and permanent withdrawal of the drug), proteinuria, hematuria, oliguria, anuria, renal failure with azotemia, glomerulonephritis, acute tubular necrosis, nephrotic syndrome, bilateral renal cortical necrosis, renal stones, ureteral obstruction with uric acid crystals due to uricosuric action of drug, impaired renal function, cardiac decompensation, hypertension, pericarditis, diffuse interstitial myocarditis with muscle necrosis, perivascular granulomata, aggregation of temporal arteritis in patients with polymyalgia rheumatica, optic neuritis, blurred vision, retinal hemorrhage, toxic amblyopia, retinal detachment, hearing loss, hyperglycemia, thyroid hyperplasia, toxic goiter, association of hyperthyroidism and hypothyroidism (causal relationship not established), agitation, confusional states, lethargy; CNS reactions associated with overdosage, including convulsions, euphoria, psychosis, depression, headaches, hallucinations, giddiness, vertigo, coma, hyperventilation, insomnia; ulcerative stomatitis, salivary gland enlargement. (B)98-146-800-F (10/71)

President's Letter

Casting Stones

My personal observations of drug use, abuse, and the drug subculture have caused me grave concern. I have been unable to substantiate as true much of what I was taught and until recently, much of what I read. Cullen's historical article in this issue* with the benefit of hindsight, relates several instances where organized medicine's positions on marijuana were inaccurate or may have been culturally biased.

Recently NBC produced "What Price Health." Medicine's reaction was instant and factual. Bias and inaccuracies utilized in support of a specific cause, i.e. Kennedy's health care delivery system, resulted in a point by point rebuttal.

The common denominator of these unrelated instances is objectivity and reminds me of Jesus's teaching, "Let him who is without sin cast the first stone." Each of us has a right to an opinion and a right to act in support of that opinion especially concerning important social issues including health care and drug abuse. Those rights should not be exercised unless coupled with the responsibility of becoming knowledgeable of the subject under consideration. As physicians, our professional opinions will stand the test of time most often if we are scrupulously honest in labeling them as factual or conjectural or as mixtures of both. To act otherwise would be to cast a stone.

Chemical Dependency*

An Overview

REYNOLD A. JENSEN, M.D.†

THE TIME—Summer of 1967. The place—the Haight-Asbury District, San Francisco. The Occasion—The Summer of Love.

Thousands of young people from every corner of the U.S.A. gathered to celebrate "The Summer of Love" and to participate in the anticipated joys of the psychedelic movement which had been gaining momentum since the late fifties. "The adolescents were naive and impressionable. Like their contemporaries in other sub-cultured settings, they had come to the Haight-Asbury with no money, expecting to be cared for in the hippie communes and planning to test themselves by experimenting with drugs. Most wanted love and understanding as well as stimulation. When they did not find it, they usually started living on the street, where they could not fend for themselves."¹

As might have been expected, the summer ended in disillusionment. The result: a rapid acceleration of the "drug problem" in other areas of the country. It is as if the "Summer of Love" was the spark which ignited the smoldering but growing problem which had been previously ignored by too many of us. Four years later, June, 1971, President Nixon declared "America's Public Enemy No. 1 is drug abuse."

The purpose of this discussion is: (1) to present a brief historical review of drug use and associated dependency, (2) to contrast the present scene from those which previously had existed and (3) to suggest a number of contributing factors to the current dilemma which confronts us all.

Historical Perspective

For reasons little understood man from time immemorial has had the "belief" that something "magic" happens when certain kinds of sub-

stances are ingested. This mystical belief still persists and may be stronger than ever before. Few of us physicians have escaped the request by our patients "give me something to make me feel better."

The process of fermentation was discovered by early man about the time he became an agriculturist, i.e. 7000 B.C. Beer and wine were used by the early Egyptians who were also acquainted with opium (1500 B.C.). The Chinese were recommending the use of marijuana as far back as 2700 B.C. and were using tea. Two thousand years later marijuana was introduced into India and later into the Near East and surrounding areas. Brandy or "burnt wine" was introduced into Europe about 1000 A.D. Ale and mead were used liberally by the Vikings.

At the time America was discovered, the Incas were using cocaine and chewing the betel nut. In Central America and Mexico peyote and certain mushrooms were used primarily for religious purposes. The process of fermentation was used to produce beers and wine. "Drunkenness" was considered a crime by the Aztecs except in the case of an older man. The North American Indian was growing and using tobacco.

With the exception of very few cultures such as the Eskimos and Australian Aborigines, man was using some "magic" substances in one form or another. Could it be man's tolerance for socialization requires something "magic" to help in the process?

Beginning in the sixteenth and extending to the nineteenth century profound social and cultural changes were occurring in Europe. Trade and travel increased as did the population. The feudal system began deteriorating which resulted in a slow but steady drift by many to the cities.

The development of the steam engine which began the Industrial Revolution in Great Britain during the eighteenth century produced profound changes in the social structure of that country

†Professor Emeritus, University of Minnesota, Minneapolis, Minnesota.

*The term "Chemical dependency" in this discussion includes the ingestion of any and all kinds of chemicals or drugs ranging the spectrum from caffeine to the so-called "hard" drugs such as heroin. The assumption is that "dependency" whether psychological or physical stems basically from similar sources. The terms "chemical" and "drugs" will be used interchangeably.

and subsequently elsewhere. Peasants accustomed to living on the land were solicited to work long hours in the factories. "The discovery of steam as a motive power has 'mechanically' forced the close packing of abodes, the dispersions of the functions of the family, the odd phenomenon of persons working and living in close proximity without the development of intimacy ties."² They with their families lived in crowded, sordid surroundings which soon became the ghettos, and with this developed increased frustrations, dissatisfactions and tensions. Alcohol seemed to provide the means for release.

In 1700 A.D. Great Britain was producing 300,000 gallons of spirits. By 1750 A.D. 11,000,000 gallons were produced, almost a four-fold increase, and with it abuses developed. These assumed such proportions that counter movements emerged to control its use. The English "Pub" System was established, and the manufacture and wholesaling of whiskey and beer was separated from retailing.

In addition to the increased use of alcohol during this period, opium in its several forms was freely available. Its use was confined largely to writers, artists and the gentry.

Circumstances were similar in the United States during this period with corresponding efforts initiated to develop effective controls. The Whiskey Rebellion represents the first organized effort to resist governmental control of the manufacture of alcohol.

Discoveries during the nineteenth century inadvertently contributed much to the current problems of abuse and dependency. Morphine was isolated in 1805, codeine in 1823 and heroin was synthesized in 1898. The hypodermic needle was invented in 1843.

Morphine was used liberally in the treatment of the sick and wounded during and following the Civil War. Many became morphine dependent. Patent medicines and other nostrums containing opium in one form or another and generous amounts of alcohol were sold cheaply without prescription in drug stores and general stores in the rural areas.

The addictive nature of opium was not appreciated until the beginning of the twentieth century. Once recognized, public attitudes toward its use changed and corrective measures were initiated. Clinics were established for the treatment of those

addicted and the national government began to develop a set of controls. Governmental action was stimulated by the marked increase in opium smuggling.

Marijuana used extensively in Mexico, Central and South America was introduced to the Western World sometime during the nineteenth century. Introduced to the United States in the twenties, its use was confined mainly to the Mexican-Americans, blacks and poor whites in the south and southwestern sections of the U.S.A.

Phenobarbital, first synthesized at the turn of the century, led the way to the development of an increase number of related compounds.

The amphetamines were first introduced in 1927. Two of the latest members of this group to appear on the scene are methamphetamine, hydrochloride and methyl-dioxy-amphetamine synthesized in 1969.

Lysergic acid diethylamide (LSD), accidentally produced in 1938, has been used primarily for medical research, and of late as an adjunct to help patients with chronic terminal illness.

Mescaline, the active principal of peyote, has been recently isolated and is available.

The tranquilizers, major and minor, and the anti-depressant chemicals have appeared on the scene as recently as the mid-1950's. Abuse in these groups has been largely confined to the minor tranquilizers.

Many other chemicals (drugs) have appeared on the market. There are many more today than were available at the turn of the century. The use of drugs is nothing new. The question may then be asked "What is so different about the present situation in 1973?"

Prior to the current scene, the number of persons taking drugs and abusing them was relatively small and confined largely to the ghetto districts of the large cities. True, others were involved, entertainers, musicians as well as a few members of the medical profession, but again the incidence was small. Today the total number of persons using chemicals in one form or another has exploded to such proportions that it is impossible to formulate an approximation.

Fort puts it this way: "If you pick 20 adults at random, the odds are that 15 of them drink moderately, two are problem drinkers and one is a desperate alcoholic. Two who use alcohol are also using marijuana; a couple are taking tranquilizers on doctor's orders and one or two has been

popping barbiturates to relieve insomnia and is perilously close to addiction. Three or four have taken amphetamines to stay awake or lose weight and are perilously close to addiction, and nearly all of them drink caffeine, another stimulant. Ten or 12 of this group of 20 continue to smoke tobacco even after the medical hazards of that habit have been amply documented. One has probably taken acid or mescaline. The children of some have snuffed glue or carbon tet for kicks (thereby risking brain and liver damage), more smoke pot and some have had LSD trips."³

He further emphasizes that approximately 500,000 to 1,000,000 of the 35,000,000 who use drugs (mostly on prescription) have become abusers; there are 10,000,000 users of marijuana and 1,000,000 have used LSD or other psychedelic chemicals.

The National Institute for Mental Health (N.I.M.H.) estimates there are 250,000 heroin dependents in the U.S.A. as of June, 1971.⁴

Of additional concern is the increasing number of children and young people ranging from age six to 30 years who are becoming involved with chemical use and abuse. A recent report issued by the Fleischmann Commission appointed by Governor Rockefeller of New York to study education in New York City states: "Nearly half of the high school students in the nation's largest public school system are on drugs, and in the junior high grades the percentage is 20 percent. This heartbreaking phenomenon is spreading with what appears to be an epidemic in suburban and rural areas as well."⁵

A similar situation is paralleled in the urban, suburban and rural schools in Minnesota.

The number of different chemicals (drugs) and combinations available today are enormously greater than at any time in the world's history. Heroin is in good supply though its availability is being curtailed by vigorous governmental action. The prescription drugs, particularly the barbiturates and amphetamines, are apparently manufactured in amounts in excess of medical requirements, for they are easily available on the street. The adulteration of drugs by the illegal vendors is a common practice which increases the hazards. The addition of strychnine and other adulterations has led to the establishment of drug analysis centers. "Almost 90% of the street samples are not as advertised. For example, illicit mescaline upon analysis may be LSD, DOM or PCP and

THC may be PCP (scrynl, a potent chemical anesthetic) or benactyzine. 'Bad' or mislabeled drugs, coupled with increased and indiscriminate experimentation, have contributed greatly to the increase in adverse reactions."⁶

The hypodermic needle has led to an increased use of the intravenous route for administration with its attendant hazards, notably hepatitis.

The cost in terms of lives, money, absenteeism is alarming. In 1971, 1,154 deaths from heroin overdose occurred in New York City.⁷ The numbers today, no doubt, have increased.

A significant increase in the number of "junkies" (an individual dependent on heroin) has resulted in a significant increase in crime ranging from assault-robbery, prostitution and dealing in illicit drugs to secure the necessary funds to maintain the habit. Costs vary from \$50.00/day upward to \$400 per day.

The National Institute on Alcoholic Abuse and Alcoholism estimates \$10 billion is the annual cost for lost work time in the labor force, and an additional \$5 billion is the cost of welfare payments and damages to health and property.

Factors Contributing to the Present Dilemma

Most significant is the profound and accelerated changes in our social order since the early forties. The demands of production during World War II brought an influx of women into the labor market which continues to the present time. Equal rights legislation recently enacted assures not only the place for women in the labor force but also equal opportunity for wages and position. Family patterning and living will continue to change.

Our national economy has shifted from an agricultural base to one of manufacturing, commerce and service. This has resulted in a population shift to burgeon the large metropolitan and suburban areas.

It is estimated one-third of the total population is mobile, on the move continuously. The majority are the skilled technician, scientific, business, manufacturing and industrial personnel including many wives and children. The population explosion which only recently is slowing down has contributed to the current scene.

We no longer reckon distance in terms of miles, but rather in terms of the time it takes to get from one place to another.

As a result a new concept has emerged, "transience" which means "temporariness," in every

facet of our daily living including our every day human relationships. "And it is precisely these relationships that, as acceleration occurs in society, become foreshortened, telescoped in time. Relationships that once endured for long spans of time now have shorter life expectancies. It is this abbreviation, this compression, that gives rise to the almost tangible feeling that we live, rootless and uncertain, among shifting dunes."⁸

It does not require much imagination to discern the dilemma of youth. "Who am I?" "What can I look forward to?" "Are there any enduring values?" "If all is transient, what is there?"

Is only youth troubled and bewildered? May it not be, if we are candid with ourselves, that *all* of us are involved with the same dilemma?

As "transcience" gained momentum, it was inevitable that efforts "to stem the tide" should emerge. As in the past it is the writer, the poet, artist, musician and on occasion the scientist who is in the forefront of change: Ginsburg, the poet, Watts, who introduced the Zen movement to the nation, Huxley, the scientist who wrote "Doors of Perception," and the Beatles, the musicians. They with many others initiated the protest by developing and encouraging a new "life style" in the early fifties. Bluejeans, sandals, long hair emphasized resistances to advancing technocracy. Pre-occupation with eastern mysticism, the new philosophy of Sartre, the French philosopher, also characterized the protest. Leary, high priest and messianic leader of lysergic acid diethylamide use as a new promise for the future, supported by generous press coverage, provided impetus not only to the further expansion of the subculture but also to stimulate an increase in chemical use. It was not long after the lysergic acid diethylamide explosion that the use of marijuana increased to be followed by experimentation with any substance which gave promise of providing "a high."

Increased interest in and use of drugs stimulated the expansion of the illicit trade which has flourished despite best efforts to combat it. The "pusher," the local dispenser, is almost ubiquitous. Chemicals are illegally produced by individual operators, adulteration is rampant and all too often drugs produced by the pharmaceutical industry are available on "the street."

"The influence of the news and advertising media has exerted its influence by emphasizing the

emotional nature of many problems. For example, the hard-sell propaganda oriented to the here and now concept of living and employed by all commercial enterprises, may have been a catalyzing factor in increasing the misuse of drugs among young people. They are particularly attuned to the notion of instant joy, instant pleasure and instant solutions to all life problems. Whether or not these results are real, most authorities agree that the tremendous and almost unprecedented early publicity given to the sensory-enhancing and psychic effects of LSD and its evangelical prophets added to the 'contagious' nature of drug taking . . ."⁹

The continuous insidious "conditioning" to accept drugs as *the* essential in solving life's problems goes on from early morning to late at night on T.V. Take a pill and presto, instant relief is yours. And you don't need a physician!

The phenomenal expansion of the pharmaceutical industry requires mention. This increase has been explained in part by the increase in the population and attendant incidence of illness, the cost of new drug production, the increased ability to pay for drugs either as individuals or by welfare agencies providing payment for the indigent and poor.

It was inevitable that the "advertiser" enter the intense struggle not only to sell the products produced but also for the physician's attention.

Irrespective of the merits of the union of the pharmaceutical industry and the "advertisers" the combination has contributed to the dilemma of the current scene.

Unknown as yet is the influence of the war in Vietnam. Known, however, is that this war is different from all others in that drugs of all varieties were easily available and freely used. The extent of abuse is yet to be determined.

Abuse leading to dependency problems and its attendant miseries is no new problem. Differences presently existing require careful study and cooperative effort to develop ways and means to place the problems in perspective, to establish priorities and hopefully to devise programs of united effort to reduce abuses with attendant sufferings and tragedies.

Willingly or unwillingly, we physicians are an integral part of the scene. Along with others we can help evolve more satisfying and rewarding ways to meet life's situations.

Dynamics of Drug Dependency

RICHARD O. HEILMAN, M.D.*

*I woo with every charm the tempter knows
I promise comfort with a secret leer
I soothe with liquid fire that smoulders with desire
And leaves the ash of caution as it glows.*

*I lead you down a path so smooth and gay
The spectre at the end you do not see
Until you find you must depend on me
To fight the growing panic on the way.*

*And at the end, I leave you to your fate
To learn what I have done to you, too late!*

THIS POEM BY BASSETT has narrated exceptional insights into the dynamics of drug dependency.

The purpose of this paper is to discuss a new direction in the concept of these dynamics and to dispell the assumption that a psychological or emotional disorder causes drug dependency. Too long drug dependency has been regarded a "symptom" of an underlying personality disorder. Over the last decade workers in the field of alcohol and other kinds of drug dependencies have become increasingly perplexed, frustrated, and finally disenchanted with this theoretical construct as applied to the dynamics of drug dependency. Efforts in the field of psychiatry and psychology to relate the development of a drug dependency to a negative psychology, have been hard pressed to successfully ascribe personality types or even common personality characteristics which consistently render one vulnerable to becoming drug dependent. Attempts to correlate drug dependency and psychological maladjustment have been unsuccessful and therefore, indicate an erroneous, useless concept—a concept which frustrates preventive measures and treatment efforts. One of the few facts known about drug dependency is there are as many different kinds of personalities developing this problem as there are different kinds of people. The proportion of individuals in an alcohol or other drug dependency treatment unit having significant psy-

chological problems is no greater than the proportion of psychologically disturbed people in society. No longer can alcoholism or any type of drug dependency be regarded as a consequence of an underlying psychiatric disorder.

Consider the acceptance of our society of intoxication as an institutionalized form of problem solving. Ninety three million people use alcohol. The majority use it recurrently as a tranquilizer or tension reducer. The utilitarian effect of this drug is exploited as a socially accepted medication. The great majority of drinkers do not become alcoholic. Millions use sedative tranquilizers to cope with the day and sedatives to induce sleep at night as a way of solving problems of anxiety or sleeplessness. The great majority do not become physically or psychologically dependent on drugs. Thousands use intoxication by stimulants to help solve the problem of overweight. Few become psychologically dependent. Therefore, the simplistic model which states that using a chemical substance to resolve or escape from a problem is the cause of drug dependency is seriously inadequate. Could drug dependency be explained on the basis of something intrinsic in an individual? Could it stem from a healthy intention, motivation, drive, or need? Historically man has used great varieties of herbs, roots, leaves, plants, ferments, extracts, and finally synthetic substances to aid him in experiencing and perceiving the world and himself in other dimensions. Substances apparently provided man a short cut to this human capacity as he increasingly lost the ability to make these experiences available to himself. A recent book *The*

*Coordinator, Drug Dependency Treatment Program, Veterans Administration Hospital, Minneapolis, Minnesota and Assistant Professor of Psychiatry, University of Minnesota Medical School.

Natural Mind by Weil,² presents a new and fascinating concept. Namely that man has always had a strong innate drive and capacity to experience many different levels of consciousness. This need is as vital to mental health and a fulfilled life as the satisfaction of any innate need. Though Weil presents a formidable discussion to substantiate this as a credible idea, it lacks, measurable scientific evidence. Empirical evidence however, suggests support to the theory. Reference is made to Weil's theory only to interest the reader in the positive dynamics of recreational drug use and dependency. It is not my purpose to dwell on Dr. Weil's sophisticated theories but to discuss the special unique response some people have to drug use and to relate this hopefully to the dynamics of drug dependency.

A symptom of drug dependency seldom described or discussed in the literature is "preoccupation." Preoccupation is a recurrent cognitive and emotional experience human beings have when they discover something in life which becomes profoundly meaningful to them. Preoccupation with money, power, and sex is a daily experience for many people. Falling in love with someone and the recurrent preoccupation of thinking about the loved one throughout the day is probably the best example for us to understand the nature of preoccupation. The persistence of the image of the loved one recurrently invades conscious thought followed by intense feelings of warmth, tenderness, love, and desire, blocking out all other thoughts.

It is proposed that becoming enamored with the experience of "getting high" is similar "to falling in love." Recurrent preoccupation with the next time "to get high" is the first symptom and the hallmark of drug dependency. Preoccupation with the drug and the "high" is of such consequence that, if it could be objectively measured and evaluated, diagnosis of drug dependency could be established by measuring its intensity and frequency. Herein lies the difficulty in recognizing early drug dependency before complications develop to make it obvious. Preoccupation is wholly a subjective experience, one can only try to determine its presence, and when so determined, then proceed with questioning regarding the pattern of use of the drug to reach a diagnosis.³ Preoccupation was considered only to further suggest that its development seems to result from more than just the reduction of negative feelings. The drug dependent *reaches*

for rather than is *driven to* alcohol or other drug use.

Drug dependency has four characteristics: (1) An overwhelming recurrent urge to repeat the experience of intoxication—a loss of choice. (2) The strength of this urge transcends innate needs or learned needs. It is so powerful it achieves primacy as a need which requires recurrent fulfillment. (3) The urge to repeat the experience of intoxication becomes autonomous. No external or internal stimulation is necessary to trigger it. (4) Once an individual has become psychologically dependent on a drug there is no so called "cure." The experience has become so deeply imbedded or indelibly etched in the person's experience it can never be consciously or unconsciously "forgotten." Bejerot⁴ has stated, "Addiction has the strength and characteristics of a natural drive; it may be considered as an artificially induced drive developed through chemical stimulation of the pleasure center."

Only by understanding these characteristics will the dynamics based on the positive reinforcement for the pleasures of intoxication be clear and creditable. One, who becomes psychologically dependent, must experience a very exceptional pleasure in intoxication which is qualitatively and quantitatively different. It is the crucial and predominant factor in the causation of drug dependency. Terms used to describe this exceptional quality of intoxication are "champagne effect," "Cloud 9 effect," "tincture of ecstasy," "total body orgasm" to mention a few.

Though little understood, drug idiosyncrasy, when it occurs in treating patients, is meticulously respected. Mood and/or mind altering drugs have comparable reactions in some individuals. In illustration, the most widely used drug, with which most physicians have had experience, is alcohol. Individuals who drink alcohol may react in one of several ways:

A small percentage of people have a definite adverse reaction to the effects of alcohol. After ingesting an ounce or two they may experience disagreeable symptoms such as a tingling or numb feeling in various parts of the body; a headache of a throbbing variety; nausea, and vomiting. They may find the loss of mental and physical efficiency disagreeable. Because of this adverse effect they do not drink, even under social pressure. It makes them ill, "Why"?

Some who drink experience no particular pleasure or euphoria nor any significant sedative or relaxing effect. They may drink occasionally under social pressure.

By far the largest group are the social drinkers. They experience a positive euphoria or pleasure and a significant degree of tranquilization or relaxation which is enjoyable. They do like to drink, not only for its positive psychological and physiological reaction but also for the powerful symbolic meaning of communality involved in doing so. However, social drinkers, when confronted with a possible danger in any area of their life—be it physical, psychological, social, family, or economic—are able to control it or relinquish its use with reasonable ease.

It is generally agreed that one out of ten who drinks becomes an alcoholic. The positive pleasure of getting "high" is observed to be qualitatively and quantitatively different in such an individual. For reasons as yet unknown, alcohol acts predominantly and paradoxically as a stimulant rather than a sedative or depressant. The alcoholic's drinking begins where the social drinker's terminates. For a long time the mystery of the remarkable capacity of the alcoholic to drink enormous amounts and remain remarkably efficient physically and mentally has evaded us, but the fact of his unexplainable tolerance has been demonstrated. Davis and Walsh⁵ theorize that acetaldehyde from ethanol metabolism alters dopamine pathway, resulting in formation of morphine-like alkaloids. A decade of research has led them to postulate that alcohol metabolism follows a different pathway based on individual constitutional variation. Currently investigation by eight different medical research centers in the field of drug dependency (besides alcoholism) is designed along this theoretical line. Narcotics, stimulants, sedatives, and hallucinogens have different effects on different people which cannot be explained on a psychological basis. Therefore, any theory of dynamics of drug dependency must begin with the premise that the drug dependent individual experiences an "exceptionally" different response from the "average person."

The acceptance of this premise does not exclude psychological or sociological factors in the dynamics of drug dependency, whether they be of positive or negative characteristics. They, however, are secondary to the difference in drug response! The drug has to be available and circum-

stances of its use have to be reasonably favorable dependent on the orientation of the particular group or society with which he is identified. Society presently constitutes fertile soil for development of drug dependency.

Milam has convincingly emphasized predisposing neurological physiochemical considerations as primary factors in drug dependency.⁶

Experience with many thousands of alcohol and other drug dependent people reveals a remarkably similar pattern in the development of most cases of dependency, as illustrated in the case of "Mike."

Mike is anybody who could come from the ghetto, urban society, a small town, or suburban area. He could come from a family of any size, any means, any creed or religion, and any ethnic background. His value system, interests, philosophy, and goals in life could be of any persuasion. The only specific requirements for Mike to become drug dependent are that he is social minded and values the opinion of his peers. He could come from a family which has a positive attitude about drinking and uses alcohol in responsible ways, from a family which accepts heavy abuse of alcohol, or a family which prohibits use of alcohol. Mike may or may not have had prior drinking experience within the family setting. In his early teen years, generally in the company of his closest friends, he surreptitiously experiments with alcohol probably obtained from a parental or illegally acquired supply. Under the cover of darkness, in somebody's car, or behind the school, he drinks with considerable curiosity and significant excitement. The majority of his peer group approves of this behavior and promotes it persuasively. The drinking is done in an atmosphere of mutual trust and friendship. For Mike, the first experience of intoxication is exciting, adventurous, stimulating, joyful, and may be hilarious. The remarkable feeling of well being Mike experiences exceeds or at least equals any personal experience he has had. Though he may later become ill or experience a hangover, such side effects seem incidental to the enriching experience of getting "high." In our society Mike has no reason not to repeat the experience as often as possible. Ultimately he makes a commitment to incorporate the experience of alcohol intoxication into his life style—weekend dances, activities, stag parties, beach parties, or celebrations of any kind. It is this acceptance and commitment to enjoying the state of intoxication

which marks the onset of psychological dependency on getting high. It is easier to understand drug dependency if this initial commitment to this positive pleasure is understood. To quote again, "I woo with every charm the tempter knows and I lead you down a path so smooth and gay"¹ is the beginning of drug dependency.

It is at this point in Mike's life that he repeats the experience of getting high whenever it is convenient to drink "socially." Within the next six months to two years Mike will repeat the experience of getting high sufficiently often so that he develops an irreversible psychological need to repeat the experience.⁷ In the youth drug culture of today it is an easy step for Mike to use other substances to experience other kinds of intoxication. Intoxication is the "hooker" in drug dependency and whichever drug accomplishes this becomes a part of the drug dependency game of intoxication. As time goes by, Mike inevitably encounters an infinite variety of dependency complications. They may be physical, social, legal, marital, or economical problems. Ultimately he uses intoxication as a refuge or an escape from the attendant tensions. The use of intoxicants as a refuge or problem solving technique, "to fight the growing panic on the way,"¹ serves to reinforce secondarily, the primary psychological dependence. What we have at this time in Mike's life is a psychologic dependence based on positive rein-

forcement for pleasure and a secondary psychic dependence on the drug experience based on negative reinforcement to avoid pain. The trap is now complete and Mike is hooked. Recurrently he will encounter complications of tragic magnitude and variability. As all human beings abhor being rendered helplessly dependent on anything, Mike will develop an elaborate system of defense to protect himself from acknowledging he has been rendered dependent on drugs. Repression, rationalization, projection and denial are the defense mechanisms most often used. Typically these are so successful in accomplishing their purpose that Mike is the last to appreciate his dilemma. In addition, getting "high" becomes a "people" substitute with the tragic result Mike experiences recurrent depression, anxiety, and sometimes despair at his feelings of alienation and loneliness. Mike loses his skill to communicate meaningfully with "important" others, and he remains in a suspended state of growth. Rendered unstable, Mike's immature feelings and inadequate methods of relating to others emerge to dominate his total personality. It is painful to be with Mike because he exhausts people with his egocentricity. Mike's need for interpersonal intimacies go unmet and his tragedy is complete. "And at the end, I leave you to your fate to learn what I have done to you, too late."¹

Health Professionals Drug Abuse Education Project

In 1972 the subcommittee on Alcoholism and Drug Abuse of the Minnesota State Medical Association, (MSMA) supported a request for funding through the National Institute of Mental Health of a Health Professionals Drug Abuse Education Project for Minnesota and contiguous parts of adjoining states. One of the co-directors of that project, Robert G. B. Bjornson, is a member of the Subcommittee, and the other co-director is William Hodapp, Assistant Professor of Clinical Pharmacy, and Health Sciences Coordinator for Continuing Education. The aim of the project is to provide educational opportunities for health professionals in drug-related matters. The team presented its first evening workshop in Hibbing and its first general seminar in Duluth in January. Information about this project may be had from:

Behavioral Aspects of Drug Dependence

ROY PICKENS Ph.D.* AND RICHARD A. MEISCH, M.D., Ph. D.*

MOST BEHAVIORISTS view man's activities as being controlled by consequences. Acts that are rewarded are repeated, and acts that are punished are avoided. Not everyone finds the same events rewarding or punishing, however, but in general most people are similar in what they like or dislike.

In the experimental analysis of behavior, events that function as rewards by strengthening the behavior they follow are known as *reinforcers*. A number of events will function as reinforcers of behavior. Some of these (water, food, sex) are directly related to the survival of the individual or species. Others (social attention, praise) are not so directly related to biological function, but serve as powerful reinforcers nonetheless.

Certain drugs can also be viewed as reinforcers, since the behavior leading to their use will tend to be repeated.^{1,2} The reinforcing effects of these drugs strengthen the behavior leading to their administration, thus producing "drug-seeking" behavior in the same manner that food functions as a reinforcer to produce "food-seeking" behavior in a hungry organism. *Psychological dependence* is the term that refers to drug-taking behavior that results from the reinforcing property of drugs.

How is reinforcement involved in drug dependence? First, as mentioned above, drugs can serve as reinforcers in their own right, strengthening the behavior that leads to their presentation. Secondly, drug use can make other types of reinforcers available to the individual. Finally, drugs can increase the reinforcing properties of available reinforcers.

Drugs as Reinforcers

Drugs can function as reinforcers by producing a pleasurable state (positive reinforcement) or

terminating an unpleasant one (negative reinforcement). With chronic, high-dose use, opiate and depressant drugs cause physical dependence. If the administration of these drugs is abruptly discontinued, the individual experiences the aversive state of withdrawal. Resumption of drug use will terminate the withdrawal symptoms, and thereby serve to reinforce the behavior of drug taking. That these drugs also have positive reinforcement characteristics is suggested by the fact that individuals will persist in their use sometimes under conditions that do not result in physical dependence.

The chronic, high-dose use of other classes of drugs (e.g., stimulants, hallucinogens) does not produce physical dependence like that seen with the opiate and depressant drugs. The use of stimulants and hallucinogens is therefore controlled primarily by the positive reinforcing characteristics of these drugs.³

Drugs and Other Reinforcers

While drug taking is maintained by drug-reinforcement effects, it is also maintained by other extrinsic reinforcers that drug use provides. Drug use, particularly in adolescents, is often accompanied by strong peer group interest and approval, both powerful reinforcers in their own right. On the other hand, failure to use drugs may yield peer group contempt and disapproval. Both factors could explain why certain drugs are taken with no known psychoactive constituent (e.g., in smoking banana peel).

Making Other Reinforcers More Reinforcing

Frequently, drug taking is maintained by the change it produces in the individual's other behavior. Psychoactive drugs typically cause a variety of behavioral effects. If the individual should find one of these reinforcing, it would indirectly strengthen the behavior of drug taking.

*Psychiatry Research Unit, University of Minnesota, Minneapolis.

Preparation of this manuscript was supported in part by U.S.P.H.S. Research Grants MH-14112 and MH-20919 to the University of Minnesota.

For example, alcohol tends to release behavior being suppressed by fear of punishment. For this reason it is frequently served at parties to "break the ice" and thereby increase social interaction. Since most people find increased socialization reinforcing, the use of alcohol can be maintained by this indirect action of the drug. Other drugs can also have similar effects on drug-taking behavior.

Reinforcers as a Class

What makes a drug, or any other event for that matter, function as a reinforcer? Why does cocaine or heroin serve as a reinforcer, while another drug does not? At present nobody knows. A number of events are known to function as reinforcers in animals, and considerable research is being conducted to determine the physiological and biochemical changes that correlate with reinforcing effects. At present, however, we simply do not know what unique biological or physical characteristic of an event endows it with behavior-controlling properties.

Some people have suggested, at least at the human level, that a reinforcer is any pleasurable event. However, they are then faced with defining what is meant by a pleasurable event. Since no one has been able to do so satisfactorily, little is accomplished by such a definition.

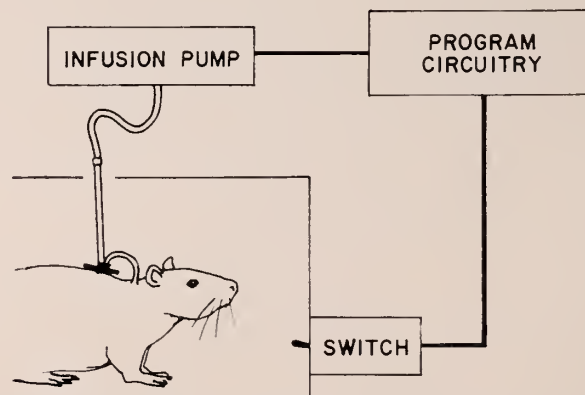

Reinforcement is a description of a behavioral process, in which an event comes to strengthen the behavior it follows. Thus, a reinforcer is not determined *a priori*, but rather by its effects on behavior.

Advantages of Reinforcement Interpretation of Drug Dependence

What, then, are the advantages of viewing drugs as reinforcers? There are actually three important benefits derived from doing so. The first is that the application of the concept makes the behavioral study of factors controlling drug dependence experimentally possible. Previously, drug-taking behavior was considered to be a problem of the mind, the result of a disorganized or sick personality. It was believed to be controlled entirely by factors which lay within the organism, and were therefore not amenable to scientific study. The reinforcement interpretation of drug dependence, on the other hand, views drug-taking behavior as the result of a number of objectively-defined variables which have already been found to control behavior in general. Whereas the effects of such variables can be experimentally determined on drug-taking behavior, the effects of the mind cannot. The concept of drugs as reinforcers has therefore led to a change in emphasis on the factors which control drug-taking behavior.

Predictive Significance

The second advantage of the reinforcement interpretation of drug dependence is in suggesting methods for predicting the dependence liability of drugs.⁴ According to this interpretation, since dependence-producing drugs are drugs which serve as reinforcers, techniques which demonstrate the reinforcing properties of drugs can therefore be used to assess drug dependence liability using ani-

Figure—Apparatus for studying drug dependence experimentally in animals. A level press activates an infusion pump for a specified time, delivering a fixed amount of drug solution through a chronic jugular catheter and into the animal's bloodstream. Swivel joints and flexible tubing allow the animal unrestricted movement in the cage chamber.

imals as the experimental subjects.⁵ Since one characteristic of reinforcers is to strengthen or make more probably the behavior they follow, one test of the reinforcing properties of a stimulus is to present the stimulus after each occurrence of a specific instance of behavior, and determine whether the behavior increases in frequency and has therefore been strengthened. If the frequency of responding increases, then the stimulus can be said to be serving as a reinforcer.

For example, if food is presented each time a hungry rat presses a lever, then the frequency of lever pressing will increase, indicating that food is serving as a reinforcer. Likewise, if each lever press results in the administration of a drug and the frequency of the lever pressing increases, then the drug can also be said to be serving as a reinforcer and therefore would be expected to possess dependence liability. If the frequency of lever pressing does not increase, however, then the drug is not effective as a reinforcer, and consequently it would not be expected to produce dependence.

In the lever-pressing situation, since responding by the animal is responsible for the drug delivery, the animal can be considered to be self-administering the drug. Consequently, these methods are called drug self-administration techniques. The Figure shows a schematic representation of the apparatus used in the study of intravenous drug self-administration by rats. The Table shows the drugs found to be self-administered by animals using the self-administration technique. As can be seen, animals self-administer essentially the same drugs that humans abuse.

Recently, rats have been found to self-administer the levo isomer of both amphetamine and methamphetamine, which humans apparently do not abuse.⁶ This finding suggests that *l*-amphetamine

and *l*-methamphetamine have reinforcing effects, and that the absence of abuse reports of these drugs in humans may be related to drug availability, peripheral side effects, or other factors.

It is interesting that the behavioral characteristics of animals' self-administering drugs are very similar to those of humans dependent on the same compounds. This latter point can be illustrated by comparing the self-administration of stimulants by the rat with stimulant dependence in man. With rats, the self-administration of stimulants is characterized by responses which are separated by long but regularly-spaced intervals. The length of the interval between successive self-administration responses is determined primarily by drug dose. When infusion dose is increased, the interval between responses also increases, and consequently fewer drug infusions per hour are taken. Similarly, when infusion dose is decreased, the interval between responses also decreases, resulting in more infusions being taken per hour. The effect of this behavioral regulation is to maintain an almost constant rate of drug intake.

A second characteristic of stimulant reinforcement in rats is the appearance of drug intake and abstinence cycles. Periods of drug intake typically last for 6-48 hours depending on the drug used, and are followed by abstinence periods lasting two to 24 hours. During drug intake periods the animals are highly excitable, do not eat or sleep, and for the most part engage in rather stereotyped body movements. Chewing of the front feet is typical under high drug doses. During abstinence periods the animals initially sleep and eat, followed by apparently normal behavior. Following an abstinence period of several hours, a new drug intake period will begin. Drug intake periods start abruptly with regular spacing of responses.⁷

With humans, similar patterns of behavior have been observed during intravenous stimulant dependence. Drug injections are regularly spaced, and periods of drug intake alternate with periods of abstinence. For example, the following pattern of intravenous amphetamine abuse has been reported for humans. "The drug is injected about every two hours around the clock, for a period of three to six days during which the user remains awake continuously. . . . Following a 'run' he 'falls out,' that is, he becomes so exhausted, disorganized, tense, or paranoid he ceases using the drug and goes to sleep. . . . The sleep lasts 12 to 18 hours following a three or four day 'run'.

TABLE

Drugs Self-Administered by Rats (R) and Monkeys (M)

morphine (R, M)	thiopental (M)
etonitazine (R)	cocaine (R, M)
codeine (R, M)	d-methamphetamine (R, M)
dihydromorphine (R)	l-methamphetamine (R)
methadone (R, M)	d-amphetamine (R, M)
meperidine (M)	l-amphetamine (R)
pentazocine (M)	SPA (M)
phencyclidine (M)	phenmetrazine (M)
ketamine (M)	methylphenidate (R, M)
ethanol (R, M)	pipradrol (R, M)
amobarbital (R, M)	tranlycypromine (R)
barbital (M)	nicotine (M)
methohexital (M)	caffeine (M)
pentobarbital (R, M)	hashish (M)
chlordiazepoxide (M)	Δ ⁹ THC (M)
secobarbital (M)	

However, the more extended the 'run', the longer the recovery sleep lasts. . . . Upon awakening he is famished, his paranoid state is largely dissipated, but he is still lethargic. At this point he is ready to resume the use of his drug. Reinjection terminates the lethargy and a new 'run' has started."⁸ As this description illustrates, the characteristics of stimulant self-administration are similar for both the rat and human, which adds supporting evidence to the validity of these techniques in predicting drug abuse liability.

Research Directions

A third advantage of the reinforcement interpretation of drug abuse is in suggesting future avenues for drug-dependence research. If drugs are serving as reinforcers, then they should possess many of the same characteristics that other reinforcers possess. Since behavioral psychologists have been investigating reinforcement phenomena for almost 70 years, much is known about the factors influencing it.

A number of factors are known to be determinants of behavior, including both genetic and environmental conditions. Antecedent variables that affect behavior and therefore could be expected to influence drug dependence include past drug history and motivational level. In this regard, prior experience with the drug or drugs in general, tolerance, and time since last drug administration in physically dependent organisms may be related to the probability of drug use.

Another class of variables includes current environmental circumstance. Specific environments (e.g., aversive, isolated, social) may define the conditions for the self-administration of different classes of drugs. By frequent and repeated association with drug use, certain aspects of the environment may also come to control drug use, increasing the probability of drug use when those aspects are present. Consider the rather high recidivism rate with alcohol and heroin after release from treatment. When returned to the former drug

environment, the stimuli associated with drug use frequently appear too strong for the individual, and drug use is resumed. Successful treatment of drug dependence could be enhanced if the environmental control produced by stimuli associated with chronic drug use could somehow be weakened. Such an approach has been taken for alcoholism in a pilot investigation with encouraging results.⁹

Reinforcement variables are yet another class of behavioral variables that may be expected to influence drug dependence. The type, magnitude, delay, and schedule of reinforcer presentation are important in determining behavioral effects. Reinforcer type and amount are inextricably found in drug dependence. That some drugs are more reinforcing than others is indicated by the "dependence liability" or probability that use will lead to dependence on a given compound. Also, since the magnitude of a drug's effect is related to administration dose, it is not surprising that relatively high doses are most frequently employed in illicit drug use.

Delay and schedule of reinforcement are also important in determining the rate at which drug dependence is acquired. Perhaps the greatest appeal of drugs is the immediacy and consistency with which they produce their effects. The shorter the delay between drug use and onset of effects, the faster will be the acquisition of drug-taking behavior. For this reason, intravenous drug use represents the greatest risk for producing dependence because of the immediacy of its effects.

Since the knowledge obtained can be applied to the study of drugs as reinforcers, we can expect the same factors which are operating in the acquisition, maintenance, and elimination of behavior controlled by other reinforcers to be involved in drug reinforced behavior. Research to date has repeatedly confirmed the reinforcement interpretation of drug dependence. Perhaps these findings can be applied in the near future to the development of new methods for understanding, controlling, and hopefully preventing drug abuse.

Federal Response to Drug Abuse

GORDON T. HEISTAD, Ph.D.*

FEDERAL EFFORTS toward control of drug abuse were directed almost entirely at the supply side of supply/demand equation until the past half dozen years. About twenty years passed between the passage of the Harrison Act in 1914 and the establishment of two federal hospitals for treatment of narcotic addicts at Lexington and Ft. Worth. For thirty more years these two hospitals represented the entire (largely unsuccessful) federal effort to control drug abuse by reducing the demand for abused drugs. Finally, in 1966 the Congress passed the Narcotic Addict Rehabilitation Act with provisions for federal civil commitment of addicts undergoing treatment for their addiction and authorizing the funding of a few pilot programs in addict treatment on a voluntary basis. Several federal agencies began to develop significant programs to deal with various aspects of drug abuse by 1969 as indicated in the Table.

Federal funding for drug abuse control programs has mushroomed since 1969 to a present estimated annual level of nearly 600 million dollars in direct allocations. As these federal activities related to drug abuse began to accelerate, the Administration requested and the Congress established the Special Action Office for Drug Abuse Prevention in the Executive Office of the President. Its mission is to mobilize federal resources, set priorities on the "demand" side and coordinate such activities with law enforcement efforts to

deal with the "supply" side of the drug abuse equation.

Federal Law Enforcement

From the passage of the Harrison Act in 1914 to the Controlled Substances Act 1970, the federal approach to drug abuse law enforcement was one of consistent increases in the penalties for the possession and/or sale of controlled substances. The 1970 act began what might become a federal trend toward continued increase in penalties for major drug trafficking with selective decreases in penalty structure for possession and use of the controlled drugs. Penalties now vary from a one year prison term with a possibility of probation and expungement of the court records for first possession offenses to prison terms ranging from two years to 30 years for sales of the controlled drugs. Such penalties are doubled for sale to a minor. The ultimate penalty of life imprisonment is still provided for a continuing criminal enterprise involving sale. A special provision of that law specifies that the distribution of a small amount of marihuana for no remuneration shall be subject to the penalties which apply for simple possession.

A substantial portion of the increased funds for law enforcement has gone to provide increased personnel and support for the investigation and prosecution of those who possess and/or sell controlled substances within our national borders. However an increased proportion of recent funding is now being directed toward diplomatic efforts

TABLE
Approximate Federal Drug Abuse Budget Allocations By Functional Category
(Millions of Dollars)

Category	FY 69	FY 70	FY 71	FY 72	FY 73*
Law Enforcement	\$32.1	\$48.0	\$85.3	\$164.4	\$229.0

*Professor and Director of Drug Information & Education Program at the University of Minnesota, Minneapolis, Minnesota.

to curtail the foreign production and distribution of illicit drugs intended for United States consumption and for increased efforts to curtail the importation of such substances at our national boundaries.

Despite the much publicized recommendation of the National Marihuana Commission for decriminalization of private possession of that drug, there seems to be no evidence of compromise in the administration's opposition to such an action at this time. The official position of the Executive Office of the President as stated in its most widely distributed educational publication on drug abuse is:

"There is not enough information to estimate the adverse effects of marihuana if it were to be used on the same scale as alcohol. . . . Since it seems to be true that once a drug becomes an accepted part of the social fabric it is almost impossible to prohibit its use, many concerned citizens feel it is prudent to await the results of ongoing and planned studies before treating marihuana in the same way as alcohol."¹

Federal Treatment and Rehabilitation Programs

The federal drug abuse treatment effort is aimed primarily toward rehabilitation of narcotic addicts. To a large degree this reflects the administration and public concern for the high rate of property crime associated with heroin addiction. However it also reflects the relative dearth of evidence to substantiate the effectiveness of treatment programs for those who are dependent on or otherwise abuse drugs other than the opiates. Among the abusers of other drugs there is some federal support for therapeutic communities which emphasize drug abstinence, often in the traditions of alcohol treatment programs, and a somewhat larger support base going into crisis intervention programs in which the typical emphasis is upon minimizing the damage from drug use rather than upon total abstinence.

No one can doubt the authenticity of examples in which individuals have come out of therapeutic community and/or crisis intervention programs to lead dramatically changed and constructive lives. However there is a great deal of other evidence suggesting that a high rate of usage of many non-addicting chemicals is often temporary with or without treatment. The evidence suggesting that the treatment was crucial in the rehabilitation of graduates from such programs is largely testimonial in nature offered by charismatic leaders of

the treatment effort in a form that is not convincing to those who allocate treatment budgets. The continued funding of such treatment programs represents a belief among federal planners that they are of some value but the modest level of such funding is a reflection of doubts that can be dispelled only by systematic research of a kind that is not typically conducted or even permitted by charismatic treatment leaders.

Although systematic therapy evaluation in the treatment of addiction is also of limited amount and quality, there is convincing evidence that society benefits from heroin treatment programs at least through reduction of property crimes engaged in by untreated addicts in their effort to support the heroin habit.²

According to a Justice Department report³ it is probable that the public is receiving the largest crime reduction dividend per dollar from simple heroin detoxification programs. Approximately 5,000 addicts are undergoing detoxification, averaging 12 days in duration, at any given time. Although the vast majority of such addicts will soon return to their addiction, they typically remain abstinent and relatively crime free for a brief period of time and resume their heroin usage on a temporarily lower scale. The usual federal estimates conclude that at least 10% of the addict population is temporarily abstinent after detoxification at any given time. Since detoxification costs only a few hundred dollars per patient, the dividends in crime reduction are impressive.

Approximately 57,500 opiate addicts are estimated to be enrolled in some form of methadone maintenance treatment at a modest average cost of approximately \$1,500 per patient per year. Although there are arguments as to whether such treatment results in true rehabilitation, since the addicts remain dependent on an addicting substance, the social benefits to society in the form of reduced crime, increased employment, and savings in welfare, law enforcement, and court costs leave little doubt that such programs are economically sound.

A far smaller number of opiate addicts, approximately 8,000, are undergoing treatment in therapeutic communities aimed toward total abstinence. Success rates in such abstinence programs are difficult to estimate. Success rates are reported from 10% to 50% of those entering treatment while those who are responsible for such programs claim a substantially higher rate. Even though the cost

of such therapeutic community regimens is at least three times that of methadone maintenance, the federal drug abuse planners have advocated these programs as part of a multi-modality attack upon addiction. However, only a small minority of addicts will enter and remain in such abstinence programs.

An additional 17,500 opiate addicts are enrolled in abstinence programs through civil commitment on a state or federal basis. With provision of community after-care the success of civil commitment procedures appears to justify the costs which are typically intermediate between that of therapeutic communities and methadone maintenance regimens.

Almost immediately after the establishment of the Special Action Office for Drug Abuse Prevention in the White House, that office set as its first priority goal that "no one commits a crime to get drugs because he could not get treatment." In accordance with that goal, the number of federally funded narcotic treatment programs increased from 135 to 320 during fiscal year 1972. The number of addicts treated in such programs was more than doubled in the last six month period of FY 1972. Despite widespread concern that the Special Action Office would over-emphasize methadone programs at the expense of other treatment modalities, the fraction of federal treatment dollars devoted to methadone programs at the end of FY 1972 was slightly lower than at the beginning of the Special Action Office but the fraction of heroin addicts in treatment receiving methadone had increased because of the much lower daily cost with methadone as contrasted with abstinence programs.

Recently the federal government has initiated a new program, Treatment Alternatives to Street Crime (TASC) for setting up judicial and administrative procedures and increasing the availability of treatment resources within communities with a high rate of addiction to permit identification of the heroin dependent person shortly after arrest and the offering of special opportunities to enter a variety of treatment programs as an alternative to imprisonment. Organization of such a project within a community demands the active participation of city government, police, the judiciary, corrections, prosecuting and defending attorneys, as well as community based treatment and planning programs.

Federal Education and Training Programs

Appropriations for education and training in drug abuse as late as fiscal 1969 were minuscule and state and private sector investment were equally low. Even before the massive infusion of treatment dollars during the fiscal year 1972, there were large numbers of persons actively engaged in drug abuse treatment programs with no evidence of training and often with little significant drug related experience prior to their employment by such treatment programs. Advanced degrees in the health related sciences and professions were and are almost totally irrelevant to competence to deal with drug abuse health problems since our institutions of higher education have traditionally included no significant preparation for dealing with drug abuse in such training programs. Into this vacuum of specialized competence, the ex-addict and other former drug abusers were used to carry out treatment and prevention programs. To a degree probably greater than in any other health related field, drug abuse treatment and prevention is being carried out by para-professionals with a minimum of formal training.

The federal response to this unique manpower crisis has been to set up on an emergency basis seven regional training programs throughout the country for professional and para-professional workers in drug abuse treatment under the auspices of the National Institute of Mental Health. A parallel set of seven regional training centers for community drug abuse prevention teams has also been initiated by the U.S. Office of Education. These centers offer short term training of two weeks or less for those individuals who now have or shortly will have treatment or prevention responsibilities within their communities.

The National Institute of Mental Health has made available training grants to health professional schools for continuing education for graduates in the health related fields and a limited amount of pre-service undergraduate training. The National Institute of Mental Health is also prepared to fund one member of the faculty at each four year medical school for drug abuse studies and instruction.

Under federal law the licensure of drug abuse treatment facilities is delegated to the states. However it is probable that the federal government will become involved in credentialing individual drug abuse workers. Federal planners are committed to a credentialing system that emphasizes compe-

tence to perform rather than degrees or diplomas. Adequate training opportunities will be provided so that every professional and para-professional drug abuse worker will have the opportunity to meet federal standards through additional training.

The National Training Center became operational in the Washington area in June 1972 with a mission related to development and validation of training programs and techniques. Other large scale evaluations of the major drug abuse training efforts of the federal government are now in the late stage of planning and will probably be underway by the publication date of this article.

The U.S. Office of Education has been established as the lead agency for preventive education. There is no credible evidence that drug education in the schools by untrained teachers is effective. Indeed some evidence suggests a positive correlation between factual drug knowledge and at least some kinds of drug experimentation.⁴ Specialized programs aimed at specific target student groups taught by fully trained instructors may be of benefit in reducing dependence. The Drug Abuse Education Act of 1970 will expire shortly and it is probable that the Congress will infuse large scale funding into the field of preventive education in our schools, despite the lack of evidence for effectiveness of such programs.

The primary preventive education plan of the Office of Education is the "help communities help themselves" program through which individual communities (often small sections of larger metropolitan areas) are awarded small "minigrants" to send a team of five or six community leaders to one of the seven regional training centers for training. The education department of every state is also funded for pilot projects in drug abuse prevention within their school systems. The program is aimed at restructuring local communities to meet the needs of youth. A variety of community demonstration projects aimed at drug abuse prevention are also funded by the U.S. Office of Education and, to a limited extent, by the National Institute of Mental Health.

Research, Development and Evaluation

The recent appropriation of a 20 million dollar fund for development and evaluation of non-narcotic antagonists or substitutes for heroin is a clear example of a national research priority. The pervasive fear that the present administration is unalterably wedded to methadone maintenance

does not appear to be supported by such obvious research priorities on efforts to replace methadone. It will inevitably be the case that substantial portions of this special research fund will go into comparative treatment evaluation studies that could add to our knowledge of existing treatment modalities as well as the new ones based on chemical blocking agents. Although the level of funding for 'basic' research on drug abuse is continuing to increase, federal priorities are shifting toward a greater emphasis on applied studies on the effectiveness of treatment and educational efforts in drug abuse prevention. This trend is limited by the lack of scientific rigor in the majority of applied research proposals.

An Opium Pipe Dream Through a Rose-Tinted Crystal Ball

Even the most optimistic observer of law enforcement efforts to reduce the supply of drugs of abuse must admit that such efforts have not been able to deny these drugs to potential users. The seizure of a small percentage of supplies intended for the illicit consumer has a negligible effect on availability but a substantial effect on price of at least heroin. This increased cost probably encourages the rate at which addicts seek treatment or at least temporary detoxification but it also exaggerates the rate of necessary property crimes to support a more expensive habit. Criminalization of those who possess and use illicit drugs also separates the drug experimenter from alternative sources of "feeling good" through socially acceptable avenues such as school participation, employment, and social interactions with the non-using public. Criminalization of use tends to drive experimenters into dependence upon drugs because such drugs are more dependable than the "straight" alternatives in a society that treats drug use as a crime.

Although there has been some success in controlling demand through increase in availability of treatment and even some dramatic islands of success like the reduction of heroin use among Viet Nam military personnel, these are not adequate to meet the national needs. The point of diminishing returns is reached in any community where the number of addicts in treatment exceeds the availability of employment and other indicators of social acceptance rationed out so sparingly by our society to drug "criminals."

If that analysis is correct and the success rate

of treatment and efforts to halt progression from drug experimentation into dependence reach a disappointingly low-level plateau within the next few months or years, the present administration may be forced to yield to demands for a drastic policy change related to addiction and other drug abuse. The direction of such a change could be in the direction of a reversion to attempts at repression of drug use almost entirely through severe punishment. Punishment will continue to be grossly ineffective unless it can be made as dependable as the perceived subjective "benefits" derived by the drug user. Increased penalties almost invariably result in decreased dependability that such negative consequences will actually be applied.

We may, for the first time since passage of the Harrison Act, be on the verge of serious consideration to a purely public health approach to drugs which would allow civilian application of the early detection techniques employed with great success among military personnel in Viet Nam. Public

health personnel could require clinical examination of urine for evidence of drug usage *only* if drug usage is totally removed from possible criminal action. Quarantine procedures for 'carriers of the contagion' have been seriously proposed and might be implemented under a public health approach as an alternative to imprisonment.

The rapidly changing public mores regarding marihuana use might become the "trigger" for a dramatic shift in overall drug abuse policies. The administration will find it extremely embarrassing when forced into a revision of its policies on that drug unless such a change occurred within the context of a broader policy shift that would relegate the marihuana issue to a minor component of a new national public health policy relating to other drugs as well.

These speculations and views do not necessarily reflect the policies or recommendations of any governmental agency with which the author now is or has been affiliated.

Behind the Times

[Dr. Winter] had learned his medicine under that obsolete and forgotten system by which a youth was apprenticed to a surgeon, in the days when the study of anatomy was often approached through a violated grave. His views upon his own profession are even more reactionary than his politics. Fifty years have brought him little and deprived him of less. Vaccination was well within the teaching of his youth, though I think he has a secret preference for inoculation. Bleeding he would practice freely but for public opinion. Chloroform he regards as a dangerous innovation, and he always clicks with his tongue when it is mentioned. He has even been known to say vain things about Laennec and to refer to the stethoscope as "a newfangled French toy." He carries one in his hat out of deference to the expectations of his patients; but he is very hard of hearing, so that it makes little difference whether he uses it or not.

He always reads, as a duty, his weekly medical paper, so that he has a general idea as to the advance of modern science. He persists in looking upon it, however, as a huge and rather ludicrous experiment. The germ theory of disease set him chuckling for a long time, and his favourite joke in the sick-room was to say, "Shut the door, or the germs will be getting in." As to the Darwinian theory, it struck him as being the crowning joke of the century. "The children in the nursery and the ancestors in the stable," he would cry, and laugh the tears out of his eyes.

He is so very much behind the day that occasionally, as things move round in their usual circle, he finds himself, to his own bewilderment, in the front of fashion. Dietetic treatment, for example, had been much in vogue in his youth, and he has more practical knowledge of it than anyone whom I have met.*

The Street Agency

A Response to Need

SUZANNE GEISLER* AND JOHN SIVERSON†

THE PROBLEMS of alienated youth and the growth in the abuse or non-medical use of drugs has become a national concern. Many innovative programs and newly formed agencies have emerged to deal with the so-called "Drug Crisis." Governmental agencies have begun consulting with those involved in handling the problems of contemporary youth, to the point of disregarding the advice of professionals in the helping professions.

This article will explore these new problems and those who have been involved in dealing with them in terms of their historical antecedents, their development, the emergence and evolution of services, their present status and possible future. Implications for the health professional, as well as possible modes of action, will be mentioned.

How It Was

The mass media, through its coverage of Haight-Ashbury's hippie "Summer of Love" in 1967, focused national attention on the new street culture, and its growing illicit drug use. Similar signs of changing life styles soon followed in many American communities including Minnesota.

In the late '60s, young people were developing their own street culture in the West Bank area near the University of Minnesota. It was a decaying low rent area which had already attracted members of the "bohemian culture." The 10 O'Clock Scholar, a coffeehouse known for having once featured folk singer Bob Dylan, was located there. Cafe Extempore, student bars, and several "head shops"—many of which are still operating—rapidly developed.

The West Bank, like Haight-Ashbury, became a repository for unwanted people. Largely inhabited by students and the elderly, the area was rapidly deteriorating. A district long known for its derelicts and alcoholics fast became a haven for their younger counterparts. Hippies, musicians, motorcycle gangs, ex-cons, and runaways gravitated to the community. Suburban youth, when confronted with threatening problems in their home and community also were there. Others came after school and as weekend sightseers to view the "head shops" or scan the long-haired hippies.

The newcomers to the West Bank had much in common. Most felt alienated from the mainstream of society. Some had relatively low coping skills in the traditional culture. Most had low incomes. Many were dreamers and wanderers. Drug use was the main bond, ranging from simple experimentation to recreational use and abuse. As might be expected, illicit drug dealing flourished, nurtured by experimentation with LSD, amphetamines, and marijuana. As with San Francisco's Haight-Ashbury, the patterns of usage in the area progressed from hallucinogens, to amphetamines, to barbiturates, alcohol, and opiates, and finally to combinations of various drugs.

The need for health and mental health care facilities in this area became increasingly manifested due to the lack of self-care and problems relating to increasing drug abuse. Many of the inhabitants were unable to take care of their basic needs such as money, food, and housing. Acute drug crises, initially bad trips and "flashbacks" and then overdose and withdrawal, were handled not by needed medical services but by friends. Longer term problems came in the form of abscesses, serum hepatitis, "burn-outs,"[#] and dependency. Most individuals simply lived with their symptoms, treating themselves with home remedies or illicit drugs, and kept black-market tranquilizers handy when they expected to "freak out."

*Founder and former director of Pharm House. Presently she is on the staff of the Health Professionals Drug Education Project, Health Sciences, University of Minnesota, Minneapolis.

†Facilitator, Regional Training Center, University of Minnesota, Minneapolis.

The Street Agency is a recent development. Most often it is organized simultaneously in response to an urgent need and staffed primarily by volunteer youth with only a hope and prayer to initially finance the program. While there has been considerable attrition, the street agency seems here to stay.

[‡]Hippie-run shops selling everything from paraphernalia used in smoking marijuana to rock records and incense.

[#]Burn-out—mental and/or physical exhaustion from excessive drug use.

Despite the needs, appropriate help was not available. The young people refused to consult private physicians, who they assumed would overcharge them and hand them over to the law. Neither by training nor experience were medical institutions and their personnel prepared to deal with the new value systems and problems presented by alienated youth. In some instances, bad feelings were reinforced towards institutions in general by turning away individuals exhibiting overdoses and other associated problems. It was not uncommon to hear drug abusers claim mistreatment by helping agencies because of the negative attitudes displayed toward them. Given the strong attitudes many individuals in our society hold about certain types of drug-taking, such emotional responses are not surprising. A Canadian commission of Inquiry on the Non Medical Use of Drugs commented that physicians and hospital staff often lacked patience, and sometimes "... expressed hostility towards the drug user." Numerous examples of similar occurrences in this area and elsewhere in the United States have been reported.

Emergence—The Initial Response

While some physicians and others in the health professions responded in other areas of the city* the response to the West Bank difficulties was negligible. Dr. Judy Bergfalk† singlehandedly responded to the medical and emotional crises of the West Bank community with never-tiring patience and compassion. She often operated out of Sister Rita's Free Store where used clothes, appliances, books, and other items, were available free. Both old and young took advantage of the Free Store. She would treat suburban youth who were reluctant to consult their family physicians for fear of parental involvement. The law requiring parental consent to treat minors complicated the situation for both the physician and youth

*Teen-Age Medical Service, started by pediatricians connected with the Children's Health Center, opened in the fall of 1968, becoming one of the nation's first free clinics. In June, 1969, a group of mental health professionals founded Walk-In Counseling Center, a free no-red-tape crisis center. Both services are still active and functioning in south Minneapolis.

†Dr. Bergfalk—a pediatrician known to West Bank people as Dr. Judy.

‡Crash Pad—an apartment or house where an individual who has no place to sleep or pass out from drugs may remain overnight or a few days.

#Street Professional—For purpose of this paper, a "street professional" implies that an individual who, by experience and informal training had attained a significant level of competence to deal effectively with alienated persons and their difficulties.

seeking medical help. Fortunately the law has been changed.

Crash pads‡ were common on the West Bank. Eventually some became more organized and provided more than just a bed for the night. One example was the Agape House, a temporary home for runaways and outcasts which combined counseling with housing.

The Midwest's first hot-line service, Youth Emergency Service, known as Y.E.S., was organized in May, 1969.

Y.E.S. ushered in a movement seeking to respond to the critical needs of the youth culture by using knowledgeable street people to help their peers. Not only did the phone service demonstrate to the established organizations where they had been failing to respond, but it indicated how they might change and help. Y.E.S. also recruited and developed many "street professionals."#

Through experiences at Y.E.S. many volunteers became aware of needs not being met by existing agencies. Several went on from Y.E.S. to initiate new programs.

One program started by former Y.E.S. volunteers was the Pharm House, a drug crisis intervention center founded in the Spring of 1970. With the exception of methadone programs for heroin addicts and alcohol treatment programs, there was no place for a person with drug related problems to receive counseling. The Pharm House, like many other youth programs which followed, began on an experimental basis. During the summer of 1970, Pharm House carried on research to determine the extent of drug usage and the need for a treatment program. At the same time it provided emergency drug care, therapeutic discussion groups for people trying to get off drugs, and a community drug education program.

The Pharm House also initiated Minnesota's first youth-oriented residential drug treatment program, which was operated by youth. An outpatient program for drug-dependent youth and their parents was also begun.

The impact of the Pharm House and other new programs upon the West Bank community and greater metropolitan areas reinforced that of Youth Emergency Service. Most were volunteer organizations run by "street professionals." They were confronting the established institutions for their lack of responsiveness to youth. Their primary philosophies were based on the belief that peers

could help peers, and that people were entitled to proper physical and mental health care. Just as many youth-oriented programs were born out of Y.E.S. volunteers, so were many drug related programs developed by former Pharm House staff. Many new services followed. Drop-In Centers,* new phone services, draft counseling centers, etc. sprang up in 1970. Subsequently, other treatment facilities provided viable alternatives to chemically dependent persons in the metropolitan area.

The Present Status

In May, 1972 rules and regulations being proposed by the Department of Public Welfare for implementation of a licensure law threatened every program, person, and organization working with chemically dependent people, by “. . . prohibiting the operation of such facilities and services without a license; providing penalties . . .”†

These changes could potentially threaten agencies to the point of their very existence. For the first time, the established or “straight” and “street” agencies realized their need for each other.

In response to this threat, a meeting was arranged to bring together representatives of all concerned agencies active with alienated youth. Today, as a result of this effort as well as others, there is growing cooperation and coordination among agencies through a new organization, the Drug Assembly.

Since its inception the Drug Assembly has defined several goals. One impact of such a unified yet independent voice is a totally new concept of licensure. The proposed rules and regulations for licensure as rewritten are supportive of innovation and the use of “street professionals,” and will, if adopted rely more on evaluation and suggestion than censure and recriminations.

Another goal is ultimately to provide smoother continuity of care for those who rely upon drug-related services. A Drug Assembly Funding Task Force will soon present a grant proposal to the Narcotics Addict Rehabilitation Branch of National Institute of Mental Health for the funding of many agencies within a system which empha-

sizes evaluation and follow-up. It is hoped that with such cooperation, fewer people with drug problems will be “lost” between agencies.

The continuum of care concept is being reinforced by a task force concerned with the lack of detoxification services for the drug dependent in Hennepin County. It is presently arranging a volunteer service to assist the Emergency Room hospital staffs to identify the chemically dependent person and to suggest appropriate referrals.

A communications network has been established. All relevant information developed by the Drug Assembly is passed to individuals and agencies via this communication channel.

In addition to Minnesota being one of the most advanced states in the country in terms of its drug services, it also is the home of the *Exchange*, a national newsletter for hot-lines and other youth-serving agencies. The Third International Hotline Conference was held last year in Minnesota. Less clearly related to drugs, yet important to the problems of alienated youth was the National Run-away Conference held in Northfield, Minnesota in the summer of 1972.

In May, 1972, when the Office of Youth and Student Affairs of the Department of Health, Education and Welfare, selected four people to discuss youth crisis centers with Mr. Elliot Richardson, then its Secretary, two were from Minneapolis.

Future

As agencies multiply and cooperation continues, the complexion of “street agencies” will change. The original experimentation and “fly by the seat of your pants” attitude will be replaced by the increasing proficiency of the “street professional.” Established health and social service agencies will absorb some of the more experienced to the mutual advantage of all concerned. Finally, enriched training programs for the street agencies personnel and changes in the established “straight” agencies will result in increased effectiveness in service offerings to those in need.

Since the initial panic about the drug “crisis” is beginning to subside. It is now appropriate to define more critically needs and to develop appropriate methods of providing for the solutions. Prevention requires attention as does recognition that self-destructive drug abusers often are the symptom-bearers for others—their family, schools.

*Drop-In Center—Community oriented programs providing an informal and non-threatening place for youth to relax and receive counseling.

†Quoted from An Act, Chapter No. 627.

or perhaps the culture itself.

Implications for Health Professionals

There is, more than ever before, a need for increased cooperation among drug related and health care services. Cross-referral for many types of problems seems appropriate for both the institution and the client. Now that more alternatives exist, each group must take stock and decide what it can do best to serve its clientele. All must share the responsibility for defining unmet needs and developing services to meet them. Finally, it is crucial that a continuum of care concept be implemented in the areas of health, mental health, and drug abuse treatment and prevention which

span "street" and "straight" agencies, "street" and "traditional" professionals. It is the mutual responsibility of all to educate and direct those in need to the appropriate resources as well as to be informed themselves about these same matters. Street agencies must begin to provide more referrals for medical needs, and all health personnel must utilize to advantage the consultation currently available from street professionals and street agencies. Through getting to know each other better, a realistic mutual awareness of limitations and sharing of skills and expertise in these areas will emerge hopefully to the enrichment of all.

Cannabis

We should note that cannabis has in the past been a legitimate medicine in America. Why not now? Was it shown to be dangerous? No: it is astonishingly safe with a lethal dose in dogs or monkeys hundreds to thousands of times its "effective" dose. Did physicians decide, for some medical reason or reasons, that it should no longer be available for use? By no means: it was removed from the United States Pharmacopoeia and the National Formulary following passage in 1937 of the Marijuana Tax Act, against which legislation the American Medical Association spoke out vigorously through its representative, Dr. William C. Woodward. Doctor Woodward, who was a lawyer as well as a physician, was at that time Director of the Bureau of Legal Medicine and Legislation of the American Medical Association, and he pointed out to the Ways and Means Committee of the House of Representatives that cannabis should remain available to physicians for study and for appropriate use. Incidentally, with its safety, its lack of physical addictiveness and its remarkable freedom from developed tolerance in the user, it is a drug with exciting possibilities for geriatrics. It is a mild mood-elevator and an exceptional appetite stimulator, virtually free of recognized adverse effects.

How, then, has it happened that American physicians have so quietly given up the availability of this drug to the demands of government? Why have we rejected the judgment of sound medical scientists and rallied around the grossly unscientific, largely anecdotal arguments of the old Federal Bureau of Narcotics? How did we come to our current position concerning marijuana? Has our position complicated society's "pot" problem?

Perhaps we should inquire into these questions. If so, we will likely read the article by Allentuck and Bowman printed in the *American Journal of Psychiatry* in 1942, and which ends with the following paragraph:

"There is no evidence to suggest that the continued use of marihuana is a stepping-stone to the use of opiates. Prolonged use of the drug does not lead to physical, mental or moral degeneration, nor have we observed any permanent deleterious effects from its continued use. Quite the contrary, marihuana and its derivatives and allied synthetics have potentially valuable therapeutic applications which merit future investigation."

Robert G. Bjornson, M.D.
St. Paul, Minnesota

Marihuana

What Type of Problem

S. B. SPARBER, Ph.D.*

MARIHUANA officially currently has no therapeutic uses in this country but unofficially is being used by upwards of 20 or more million individuals to self-medicate themselves. This statement may be enough to rouse the profession against the legalization or the decriminalization of marihuana, if only to keep the prerogative of use of pharmacologically active agents within the purview of the licensed physician. However, aside from the fact that other medicaments, in the form of lower dose over-the-counter preparations and other "mind-altering drugs" such as alcohol, are being used by an even larger segment of society, it may turn out that the marihuana "problem" is not a pharmacological-medical one but rather a socio-legal one.

After having searched (perhaps in vain) for clearcut evidence that marihuana or its active constituents, produce untoward effects upon the human body, the biomedical evidence may have to bow to population pressures, as does the tobacco problem. Most enforcement agencies are willing to concede that the law, at least for possession and use, is unenforceable within the framework of the total population. As a result, there often is prejudicial or selective enforcement. The figures published by the U.S. government indicate approximately 10-15% of the population has used marihuana. This being the case, just about every reader of this article should know or have contact with an occasional or regular marihuana user.

Indeed, if one can rely upon questionnaire information, among four medical schools surveyed, "use" figures range from 16%-70% having tried marihuana to nearly 50% currently using the drug.

What makes the "problem" even more exasperating is the traditional reliance of legislative bodies upon organized medicine for at least partial guid-

ance in matters of this type while a view of the official stance of organized medicine (AMA) on marihuana through the last 35 years or so suggests very strongly that political expediency may have severely suppressed objectivity on this issue. An excellent treatise on the legal ramifications of the problem is Kaplan's book *The New Prohibition*.

Source or Botanical Origin

Most of the marihuana used in this country is used in cigarettes and consists of various parts of the plant *Cannabis sativa*, of which there are many varieties. Certain parts of the plant are not included in the legal description, since these parts are used in the manufacture of hemp twine or in making oil or cake from its seeds. Nevertheless, it would not be surprising if these excluded parts, from certain varieties of cannabis that have a high yield of the apparent active principle(s), contain more of the active principle(s) than included parts from the typical so-called Minnesota-green variety. Therefore, any discussion of marihuana must take into account the content of the major active constituent (Δ^9 -tetrahydrocannabinol, THC^{\dagger}) as well as various other factors to be discussed later.

Toxicity

From preclinical infrahuman, as well as several clinical observations, it is apparent that the margin of safety with cannabis and its synthetic active constituent, THC, is extremely high. Translated into pharmacological language, the "therapeutic" ratio ($\text{LD}_{50}/\text{ED}_{50}$) for man has not been determined, since there are no known deaths directly attributable to marihuana. In animals, the dose for various behavioral actions ranges from fractions of a milligram/kg to upwards of 10-20 mg/kg of THC, depending upon the sensitivity of the measure and the species. The parenteral doses of this compound (THC) necessary to produce death in some species is in the 200-500 mg/kg range acutely, with some animals participating in chronic tolerance studies surviving and

*Associate Professor, Department of Pharmacology and Psychiatry Research Unit, Department of Psychiatry, University of Minnesota.

$\dagger \Delta^9$ and Δ^1 are synonymous, depending upon which nomenclature is being used.

active at doses as high as 1800 mg/kg, showing little or no signs of withdrawal syndrome characteristic of opiate or barbiturate dependence. Higher species (dog, monkey) appear even less sensitive to lethal actions of THC than rodents. To get some perspective regarding this measure of toxicity, the therapeutic ratio for morphine (acutely) in man is on the order of five to 10. In the case of digitoxin, using toxic effects (vomiting) rather than death and ventricular slowing as the therapeutic effect, the median toxic dose has been estimated at about 30 micrograms/kg, p.o. while the median therapeutic dose was estimated at about 10 micrograms/kg, p.o. as a single dose. The above comparison is not to be construed as suggesting that cannabis or THC is pharmacologically inactive. The drug is indeed active and as shall be discussed later, its activity may lead to its use or use of synthetic congeners of THC in several specialties and subspecialties of medicine, including psychiatry and ophthalmology.

Physiological Effects

The most widely known and reliably reproduced physiologic effects of marihuana are the slight tachycardia and conjunctival injection. The reddening of eyes does not seem to be the result of irritation by smoke, since it is also produced by the orally administered compound. A more recent observation, which may lead to the compound's use in the treatment of glaucoma, is a reduction of intraocular pressure by an average of 25% in 11 subjects studied.

Although reports of enhanced appetite and desire for sweets has partially been confirmed in a laboratory setting, there is no evidence that this is brought about by alterations in blood glucose levels. Either decreased responsiveness of the glucose receptors in the central nervous system (CNS) and/or increased sociability, with our traditional proclivity towards sharing food, may be responsible for this mild effect.

Central Nervous System

Studies with radioactive THC given to monkeys have demonstrated a correlation between peak behavioral effects of the drug or metabolites and their regional distribution to limbic system structures and other areas thought to be involved in recent memory consolidation (hippocampus, amygdala), sensory perception (corpus quadrigeminum), and coordination (cerebellum). It may

turn out that the major effects of marihuana on CNS function are a reflection of its (or its metabolite) physical-chemical properties like lipid solubility, etc. and therefore its disposition within the body.

Neurochemistry

There has been a major thrust of research on the importance of the biogenic monoamines, such as acetyl choline, dopamine, norepinephrine and serotonin, and their involvement in brain function in recent years. It is therefore not surprising that studies on the effects of THC upon these transmitter compounds have been undertaken in recent years. Some studies purport to have demonstrated changes in steady state levels of some of these monoamines. Others report changes in turnover or synthesis of the compounds. Most of the neurochemical studies have been performed with extremely high doses of THC; certainly well above the behaviorally active doses for the respective species involved. It is therefore too soon to draw any conclusions as to the involvement of compounds like serotonin, which has been fairly well identified as being involved in some of the actions of lysergic acid diethylamide (LSD) and other hallucinogens, or the catecholamines, implicated in the mechanism of action of amphetamine-like drugs. There have recently appeared some reports suggesting an effect upon dopamine function, the transmitter system apparently involved in disorders such as Parkinsonism, Huntington's Chorea, and Gilles de la Tourettes' disease.

Behavioral-Psychological Effects

In animals, behavioral effects attributable to marihuana or THC range from facilitation or enhanced performance of some types of conditioned behavior to disruption or prevention of other types of behavior. Studies using more precise measures, such as operant timing behavior by monkeys, pigeons and other species, show effects at low doses that are consistent with those reported for man. Where requirements are such that the organism must delay its responding for an arbitrary period of time, more often than not, there is an overestimation of elapsed time resulting in premature responding. One of the most profound effects of THC in man is the stretching of time estimates, minutes seeming like hours, etc.

Several reports on interaction of THC with other drugs suggest pharmacodynamic, as well as

metabolic, interaction. Initial studies in animals showed enhanced barbiturate induced sleeping on the one hand as well as enhanced amphetamine induced increases in locomotor activity on the other. Various other reports in the literature further support an interaction between THC and other psychoactive drugs and it is the general consensus that THC has both stimulatory and depressant activity; either dose dependent or related to the fact that THC may be both a pharmacologically active agent in addition to being a prodrug (to be discussed along with its metabolism).

In humans, perhaps because of the rapidity of its onset of action when smoked, and many of the cues or stimuli associated with the effects of the drug, there appears to be an inordinately large learning component associated with the subjectively reported effects. Translated into clinical therapeutic terms, the "placebo" effect, especially in experienced users, is great; for example, in one carefully controlled experiment experienced marihuana users were not able to differentiate between potent cigarettes and cigarettes containing little or no THC but still smelling somewhat like the "real thing." The phenomenon of sensitization or "reverse tolerance" appears real enough in the initiate and casual user but tolerance also appears to develop in the more avid user, although as mentioned previously, withdrawal or abstinence symptoms are minimum and are similar to those of other compounds which are inducers of mild to moderate psychological dependence, not unlike tobacco.

The "reverse tolerance" is probably due to the fact that the initiate doesn't know how to perform the mechanics of deep inhalation necessary to get the greatest absorption and subsequently learns this, resulting in greater availability of THC per puff or cigarette. In addition, never having experienced the subjective, psychological effects, he does not know what to expect or look for at first (expectation). With repeated exposure, this expectation comes to play an important role in the experience, as does the nature of the environment, both social and physical. The third apparent reason for the reports of sensitization is the long half-life of THC in the body. It has been estimated that the plasma $t_{1/2}$ (time necessary for initial plasma levels to diminish by $1/2$) in naive individuals is approximately 56 hours. This means that 56 hours after the initial dose or exposure,

there is about 50% of the THC or metabolites (some of which may also be active) still in the plasma. If the user smokes another cigarette of equal potency one or two days later, he or she requires fewer puffs or cigarettes, to reach threshold or active plasma and presumably brain levels, everything else being equal.

Chronic marihuana use however, conveys a sort of tolerance to this effect in that the plasma $t_{1/2}$ now decreases to approximately 28 hours. These observations suggest an enhanced metabolism and/or excretion rate as a result of greater use.

Metabolism

The above observations, coupled with concurrent studies in animals, have led to the conclusion that the enzyme system (normally studied in liver but identified to be active in lung and other tissues associated with organs or tissue involved in protective or toxicological degradative mechanisms) responsible for ridding the body of no longer usable steroid hormones and many other types of drugs, through oxidation or reduction-type metabolism, may be alterable by THC and play a role in its action.

It has been known for many years that these microsomal mixed-function oxidases (enzymes) can modify drugs or other lipid soluble active chemicals to more water soluble, usually less active compounds, which are then more easily excreted in urine or feces. In addition, prolonged exposure to some of these drugs can cause an increase in the amount of enzymes available for metabolizing themselves and other compounds. Before this induction (increased capacity) effect is realized however, there may be competition between two or more substances that are metabolized by these mixed function oxidases and therefore result in slower or less metabolism of either or both. This phenomenon could account for enhanced or prolonged drug effects resulting in what I previously referred to as metabolic interaction. An important clinical example of metabolic interaction after induction has taken place can be seen in an enhanced effect of dicumarol (longer prothrombin time) after a patient is taken off a barbiturate (phenobarbital is a potent inducer) that he or she has been receiving along with the anticoagulant. Since the anticoagulant is metabolized more rapidly, due to induction of the enzymes by the barbiturate, when present, more of the antico-

agulant is needed to maintain an adequate prothrombin time. In the absence of the inducer, the rate of metabolism of dicumarol decreases, resulting in an *actual* increase in dose. In the case of marihuana or THC, it appears that enzymes modify the structure of THC to 11-OH- Δ^9 -THC and then to 8,11-diOH- Δ^9 -THC. The first step seems to be relatively rapid and studies in animals and more recently in man, indicate that the 11-OH- Δ^9 -THC is at least as active or more active than the parent compound. This means that 11-OH- Δ^9 -THC and the parent compound are

active, perhaps even in different directions, one being responsible for the stimulant effects often reported, the other, for the later depressant actions.

So we have a compound which itself may be potent pharmacologically as well as being a pro-drug for another potent compound, its metabolite. There are other metabolites besides the di-OH-THC and more research is needed to determine whether or not they are active. Most appear at this time to be less active or inactive.

Drugs and Early Man

Drugs have made up a fascinating portion of man's ecosystem since prehistoric times. Ancient accounts of drug use, full of fantasy, superstition, and credulity, abound in the writings of Homer and other venerable authors as well as in the unwritten traditions of primitive societies. Most of these substances were readily obtained from plants found in the immediate environment, their properties discovered by unknown individuals and under circumstances long since forgotten. Their use was perpetuated through the centuries by demonstration and by word of mouth, a part of the cultural lore by which ancient man attempted to cure his ills, alter his conception of reality, or destroy his enemies.

The systematic study of plants and drugs began with the Greeks in the era of Hippocrates and reached its classical apogee in the works of Dioscorides, a Greek physician in the Roman army of the Emperor Nero. The *Materia Medica* of Dioscorides was an exhaustive collection of short illustrated accounts of plants and their practical uses, the sum of the time's knowledge of drugs, and one of the most influential botanical treatises ever produced.

The earliest and the finest of the Greek herbals still in existence is a brilliantly illustrated volume of Dioscorides prepared about 512 A.D. as a wedding gift for the daughter of a Roman Emperor. One of the pages from that manuscript, depicts the mandrake root, thought to grow in the shape of a man's body, together with a dead dog which has been sacrificed in the ritual digging of the root. Mandrake was an early source of hyoscine or scopolamine.

Perspectives on the Drug Problem

ROBERT G. B. BJORNSON, M.D.*

EARLY IN THE 1960s, an interviewer was trying to get Ernest Hemingway to identify some essential qualities or characteristics or abilities of a "great writer." As the interviewer listed various possibilities, Hemingway disparaged each. Frustrated, the interviewer finally asked if there was no single, essential ingredient Hemingway could identify. "Yes, there is," Hemingway replied. "A person must have a built-in, shockproof crap detector." Writers are not unique in that need. Such a device should be particularly helpful in gaining and preserving worthwhile perspectives on the drug problem and, if they are indeed separate from the problem itself, on our societal responses to it. Andrew Weil has recently written that "I cannot help feeling that what we are now doing in the name of stopping the drug problem is the drug problem."¹ It is not, of course, quite that simple. Even the grammar is deceiving: the "drug problem" is grammatically singular, but it must be plural in understanding. And one of the many problems within "the problem" seems to be that we have failed to ask ourselves the right questions. It is not only that many of our answers have been wrong, but some of our questions have been wrong. And this has involved our failure to challenge or examine the assumptions upon which we have proceeded to "attack the problem." Let's consider some of them.

One clearly incorrect assumption is that psychoactive drug use is statistically deviant behaviour. We have assumed that such drug use is a minority phenomenon, while it is in fact a majority phenomenon. Statistically, the deviant person is the non-user, not the user. Perhaps, as John Brantner has smilingly suggested, we should be asking not why a person *uses* drugs but why a person does *not* use drugs. Contributing to this misconception has been the broad societal failure, or unwillingness, to recognize alcohol, nicotine and caffeine as

psychoactive drugs, and unfortunately we physicians haven't been as helpful here as we might (and, I think, should) have been. For example, even we at times say or write "alcoholism and drug abuse" rather than "alcoholism and *other* drug abuse." While to some this point may seem insignificant, it contributes to a fundamental misunderstanding. For it facilitates our viewing "the drug problem" as involving another part of society than our own, and it allows the parent who holds a martini in one hand and a cigarette in the other to berate with clear conscience his son or daughter for smoking pot. To be sure, there are legal differences, and serious ones. But those legal differences not only further the misunderstanding but have in part issued from misunderstanding.

Another invalid assumption is that drugs can be made to "go away." This idea underlies attempts to seal off borders, to eradicate wild hemp and to induce foreign governments—even perhaps by offering them substantial payoffs—to prevent the growth of opium poppies. When such efforts fail, as they thus far have failed, we simply redouble our efforts. How can we really believe, in a society caught up, as ours is, in the concept of "better living through chemistry," that we can eliminate attractive mind-altering drugs? If, as alleged, a 14-year-old boy in San Francisco was able to make methamphetamine in his bathroom or his basement, is it reasonable to expect that we can *eliminate* such drugs? What in our experience suggests that we can do that? Were we, during the years of the Volstead Act, able to eliminate alcohol? Or control it? Why, then, do we now think we can do so much better with large and growing numbers of substances, including many made in the laboratory?

A similarly-unrealistic assumption is that people who want to use drugs can be effectively discouraged from using them. Andrew Weil characterizes this idea as an impossible dream that gets us nowhere except into worse trouble.² Involved here is the absurd and pragmatically malignant assump-

*Associate Professor, University of Minnesota; Chief, Department of Radiology, St. Paul-Ramsey Hospital, St. Paul, Mn.; Member, Subcommittee on Alcoholism and Drug Abuse, Minnesota State Medical Association.

tion that what we need in controlling drug use is increased repressiveness, in the form of what Abraham Kaplan, professor of philosophy at the University of Michigan, has called "the savagery—I know no more appropriate word—of the punishments which are inflicted, or urged to be inflicted, even for what could scarcely be objectively characterized as an *abuse* of some of the drugs."³ This repressiveness is exercised primarily through laws and law enforcement, based on the rather broad societal assumption that the law is an appropriate mechanism for dealing with largely moral questions. Arthur Miller, in his fine play "The Crucible," wrote of the days of the Salem witchcraft trials, which issued in the hanging deaths of nineteen persons and the crushing to death of a twentieth. Those things were accomplished by the duly constituted authorities and with the avid support of most of the citizenry. The relevance now of our horrified reaction to that play seems obvious, and worth pondering.

A related idea is that the very drug problem itself results from excessive parental and/or societal permissiveness. Within the past three months a colleague expressed this idea to me with fervor. He had been the prior night to a meeting on drug abuse, where the main speaker had been the local chief of police. The chief had brought along some drug samples and some scare-tactic literature and a scare-tactic movie, and my physician acquaintance had come away convinced somehow that, as he expressed it to me, "the whole damned trouble is that there is too much permissiveness in the home." He obviously didn't mean that literally, for he went on to point out the need also for laws with teeth and for a tough, vigilant police force, and for staunch, implacable judges. But let philosopher Kaplan speak to this matter of permissiveness:

"What I find particularly distressing about this myth of 'permissiveness' is both its failure to recognize the basic values of freedom in our society of individuality, and also the underlying assumption of an innate depravity in the young, as though if we give them permission to live as they choose, they will inevitably choose to be damned. I think that one could very reasonably say that young people today are not ready to exercise freedom; but I believe also that one could reasonably say, neither is anybody else. None of us is wholly ready either for freedom or for responsibility.

"The social problem, in my opinion, does not stem from our failure to be more repressive. It lies, rather, in the absoluteness, and I would say

also in the emptiness and the dishonesty, of so many of the norms that society imposes on the individual. I have elsewhere had occasion to characterize American morality as, from many standpoints, a tyranny tempered by hypocrisy. What many people perceive as a repudiation of morality is instead a repudiation of the hypocrisy."⁴

Another invalid, and particularly naive, assumption is that the heroin problem is largely a matter of moral depravity in the users, that basically it is somehow a failure of the home and the Sunday school and the church to teach them well the appropriate moral lessons. Heroin is extremely big business, enormously profitable and providing powerful financial motivations. Incidentally, we should keep in mind also the big business aspects of legal mind-altering drugs. But back to heroin: part of the financial motivation is toward the paying-off of authorities. But there is much more to it than that. Heroin yields huge profits, somewhat independently of its street price. That price follows the law of supply and demand: when, whatever the reason, the supply goes down, price goes up. The higher the price to the consumer, the greater his need to support his habit through, for example, burglary and shoplifting. When heroin prices go up, those crime rates go up. Shoplifting, of course, requires a complicitous public. Millions of dollars' worth of merchandise is shoplifted annually, and this must be sold through "fences" back into society. Some of the shoplifting losses are covered by insurance, which lessens management's distress. And society seems more than ready to buy up the "hot" merchandise. All manner of things are available, and many people actually place orders for what they want. Mothers on welfare may clothe their families for winter, as may elderly persons on Social Security. Traffic in stolen goods "represents a broad avenue through which merchandise flows down the affluent society into the indigent strata. This 'Secret Domestic Marshall Plan' is perhaps one of the more successful and less well advertised poverty programs of the Great Society."⁵ So there are many who profit from the heroin traffic, and preoccupation with the "moral depravity" of the user seems patently simplistic. "Is it possible that, like another war more familiar to us all, the war against addiction is perpetuated even while it fails because of hidden economic interests which benefit from its continuance?"⁶ It is worth noting here that legalization of cannabis has good reason to be unpopular with

heroin traffickers. With cannabis illegal, the cannabis buyer can be rather safely solicited by the heroin seller: no one is likely to complain to the police that he was offered one illicit substance while he was trying to buy another! So cannabis users, currently outside the law, make up a promising "prospect list" for heroin sellers. This illegality-in-common underlies the misapprehension that "marijuana leads to heroin." Society, in choosing to criminalize the cannabis user, has itself facilitated the association of these substances—just one example of how society's responses to drugs have in fact contributed to the developing drug problem.

Also meriting scrutiny is the assumption that the solution to the drug problem lies in putting more stress on, and more money into, our programs of drug abuse education. Drug education in America has itself become big business. It has, as pointed out by Peter Hammond, Executive Director of the National Coordinating Council on Drug Education, in an address last year to the 30th International Congress on Alcoholism and Drug Dependence in Amsterdam, captured the imagination of presidents, legislators, bureaucrats, school boards, publishers, film producers and gadget makers. Huge sums have been allocated to it, and tens of thousands of people have developed significant personal and financial interest in continuance of the drug problem. It seems they needn't worry: as Hammond explained in Amsterdam, drug abuse education in America seems to be failing, and failing miserably.⁷ Fundamental to that failure has been a lamentable lack of concern with a basic question about drug education: "Toward what improved human condition should drug education lead?" A common assumption is that drug education should lead to a drug-free state and that complete success of a drug education program would mean the achievement of that state. While that assumption is conceivably valid in the abstract, it is wholly impractical: recorded history includes no society, with the possible exception of the Eskimo, free from the use of psychoactive substances. Even if it be true that the best possible use of such substances is the least possible use, should we not in our drug education programs be pragmatically aiming toward the best achievable pattern of societal drug-avoiding or drug-using conduct? And what might that best achievable pattern be? Is it not possible that we should be aiming with our drug education at the goal of dis-

crimination in both the avoidance and use of drugs—intelligent, well-informed, carefully-considered discrimination?

One of the most serious and most significant assumptions of all is that, within the framework of personal freedoms to which this country is fundamentally dedicated, forcible control of societally non-threatening actions of our citizens is desirable. In his great essay "On Liberty," John Stuart Mill made what is to me a convincing case against governmental interference with personal liberty when exercise of such liberty does not threaten others. I recognize, of course, the problems in separating the self-regarding from the other-regarding issues of various personal acts and the need for knowledge and reasoned judgment. Our Constitution and Bill of Rights protect, or seek to protect, freedoms which may be incompatible with forcible elimination of drug abuse. E. Leong Way, professor of pharmacology at the University of California in San Francisco, has pointed out that the Peoples Republic of China seems to have no serious problem with drug abuse.⁸ There indeed seems little likelihood that any totalitarian and sufficiently-ruthless state would have serious trouble with any form of social deviance, drug-related or other. Any person even suspected of deviant behaviour—and "deviant" would be defined by the state—would be eliminated. But is drug abuse control by law really a viable and acceptable possibility in the United States of America, where we might ultimately pay for such control with the irreparable loss of personal freedoms which uniquely characterize the American dream? We should soberly consider this.

An assumption rather frequently made by physicians is that the whole matter of drug abuse is a societal problem and is really not properly the province of the physician, who should concern himself with his sick patients and leave the broad social problems to the social scientists. While this view is to a degree understandable, it is not really defensible. It was (and this was initially a surprise to the author) Rudolf Virchow who said: "Medicine is a social science in its very bone and marrow . . ."⁹ And Abraham Kaplan, in answering a question from the audience following an address to the 1970 International Conference on Drug Abuse at the University of Michigan, said in part:

"In the history of medicine, as seen, at any rate, from the standpoint of the philosophy of science, we moved from a period in which disease was

thought to be localized in particular tissues or organs to a period in which we recognized the illness of the whole organism, then beyond that to the notion—a very proper notion, in my opinion—that certain disturbances require family therapy. I am now saying that awareness of the health or disease of a whole community is what is here called for. The proper question is no longer, 'What's wrong with that particular person?' or 'What's wrong with me that I let him go wrong?' but rather, 'What is wrong in this community, in which such and such segments of it try to cope with their problems in this particular way?'¹⁰

The physician who extends his concern, and his practiced skills, from individual patients to the total community and thus becomes a public health

agent, does not lose his physician identity. Nor does the physician who involves himself with social and economic and political forces with an impact on health. What, after all, determines the identity of the physician? Certainly not technique: what, for example, have the techniques of neurosurgery, radiology and psychotherapy in common? The fundamental determinant of physician identity is a sense of responsibility and responsiveness in the presence of anxiety and pain and helplessness—a clinical conscience, as Matthew Dumont has written.¹² That clinical conscience, acting in response to serious societal sickness, is sorely needed now.

Narcotic Withdrawal Syndrome in the Newborn.

Maternal narcotic addiction may result in narcotic deprivation syndrome in the newborn. Pettey described six cases in 1912; at least 51 additional cases have since been reported (Schneck).

Several observers have reported that prematurity is a frequent complication of heroin addiction. Of 18 heroin addicts in one series of cases nine gave birth to premature infants (Schneck). Clinical manifestations of narcotic withdrawal in the newborn include a high-pitched, continuous, piercing cry, neuromuscular hyperexcitability with coarse tremors and twitching of the face and extremities, increased deep tendon reflexes, incomplete Moro reflex, and in severe cases, repeated generalized convulsions. Anorexia, vomiting, and weight loss are present in some instances. Respiratory failure is a likely fatal danger. The severity of withdrawal reactions relates to the quantity, consistency, and duration of narcotic use by the mother, as well as to the period of time from the last dose of narcotic prior to the birth of the child.

Mild cases improve spontaneously after five or six days. Severe cases require treatment with gradually diminishing doses of opiates, barbiturates, or tranquilizers until neuromuscular symptoms subside and the danger from respiratory failure has passed. Whether the addiction causes permanent deleterious effects upon brain cells or foreshadows hereditary emotional instability or psychic defects is not known.

Treatment of Chemical Dependency of the Morphine Type

Pharmacological Strategies

ROBERT A. MASLANSKY, M.D.

IN MINNESOTA SINCE June of 1968 four clinics and a number of satellite units licensed by the FDA have been using methadone HCl as the main pharmacological treatment for chemical dependency of the morphine type. Approximately 400 patients were taking the drug as of November 1, 1972. What part of the opiate dependent population this represents is not accurately known. However there is data suggesting this represents 20% of the group of potential candidates for treatment.

Methadone is used in the following ways: (1) A single dose given to an acutely ill addict with the clinical diagnosis of acute opiate abstinence syndrome. Generally 20 mg. of methadone is sufficient to ablate both subjective and objective manifestations of the acute illness for five hours. The rationale for this approach is that it is humane, and provides an entry point for a patient for more definitive treatment (from here a referral to a treatment center can be made). (2) For acute short term detoxification. One of several circumstances may dictate this form of therapy: (a) A sincere request on the part of a patient to be relatively painlessly withdrawn from his habit, (b) In anticipation of incarceration where abrupt discontinuance may cause more severe illness, (c) A manipulative device to tide a patient over while his supply of cash or drugs is nil, (d) A manipulative device to secure greater sympathy from the courts if a sentence is pending. The schedule used is: 20 mg. daily for three days, 10 mg. for two days, five mg. for two days then placebo for four days. (3) For long term detoxification; theoretically all patients in a maintenance program will undertake detoxification at some point in their treatment. However, a number of stabilized well-adjusted methadone patients whose social rehabilitation has been complete choose to defer the decision to detoxify, arguing that they are doing so well that to "rock the boat now" would be pointless and dangerous. When a patient sincerely desires to become drug free the schedule is ordinarily a 10 mg. decrement in total dose per week with the last week of five mg. per day and finally

a week of placebo.

The disease model for the complex sociopsychophysiologic disorder, chemical dependency of the opiate type has modest utility only. Therefore a pharmacologic strategem, quite appropriately, must be suspect. It should be clear that detoxification schedules, maintenance schedules and dosage adjustments are only a small part of the total approach to the patient.

The decision to use a drug that shares with heroin most of the effect altering properties, certainly the dependency and tolerance liabilities, must be justified in a special way. It is not wholly satisfactory to equate maintenance therapy with methadone to maintenance therapy with insulin, digitalis or even psychoactive substances such as the tranquilizers. Opiate addiction is a chronic disorder and as in treatment for all chronic and unending diseases, several goals are sought.

The basic problem that must be met is pathologic dependency. Dependency states, both chronic and intermittent, are part of the human condition. Dependencies of varying severity are universal.

There comes a point in time when chronic overeating, cigarette smoking, alcohol consumption, cannabis use, sleeping pill and tranquilizer use become patently self-destructive.

In the case of the opiates because of their pharmacologic properties, acute physiologic dependency is rapidly acquired and use is reinforced by profound environmental and endogenous reasons.

Methadone treatment has another dimension. It serves as a microcosm for some of the social issues of our day. The right of an individual to do to himself what he chooses is in tension with the right of the state to interrupt individual action as it becomes a threat to others. Can one find the "right" time to intercept freedom? The matter of mandating a therapeutic adventure is not often an issue in clinical medicine. The only analogue may be in contagious disease. However, we do mandate social measures in the criminal justice process. Is methadone treatment then in a sense

a social manipulative devise? And another; it is possible to amputate breasts and legs, apply highly toxic and symptom producing medicine, invade patients with tubes and devices out of all human dignity. The application of continuous methadone therapy implies the same intellectual conflict. Basically it is the conflict between what is practicable and applicable and what is an ideal therapy.

While the methadone polemic proceeds other pharmacologic strategies are being developed. The use of a longer acting methadone like drug alpha methyldol having a duration of action of two or three days may supplant daily dosage. Another is the use of blockade agents of the nalline or cyclazocine type. The ongoing use of these turn off the euphoriogenic effect of opiates thus operantly conditioning the patient away from opiate drug use.

The chemical manipulation of the catachol

amine system has been reported to change the feeling tone of the opiate withdrawing person. Alpha methylparatyrosine, a non-addictive unnatural amino acid, has been used to suppress catachol amine production. The addict treated with it reports a decrease in "craving" for drugs. How this event will be shaped into a pharmacological strategem is unknown as yet, but it is conceivable that it could be used adjunctively with long term abstinence.

Opportunities are now available to reshape the social dimension of the opiate dependent person's life. Asking a chemical to provide an ambience to commence this work is appropriate. This aspect of the total treatment is a part of the medical model. We must go beyond the medical model as we ordinarily view it however. We must share the rehabilitation responsibilities with others whose expertise is in the behavioral aspects of the human condition.

It's the Law

Physician's Heart Attack after Giving Emergency Aid

A deep-sea diver was living in a pressurized tube. He was partly eviscerated when a sudden decompensation accident occurred. A physician and surgeon were sent immediately by helicopter to the pressurized tube. The physician and surgeon immediately performed emergency surgery. The operation took place under great physical and mental strain. The space was inadequate. The operation was performed with the two physicians on their knees. They had a pharmacist's mate for assistance. The operation required two hours of intense effort to save the life of the patient.

The physicians remained with the patient, pressurized in the chamber, for more than 54 hours following the surgery. The patient and the physicians were then transferred to another hospital where one of the physicians suffered what was later diagnosed as congestive heart failure, atrial fibrillation, physical exhaustion, and arteriosclerotic heart disease. This was determined to have been aggravated by long hours of work, by obesity and by excessive smoking. His attack was precipitated by the stress of the previous three days but was not felt to be a new disease.

The physician attempted to recover damages from the diving company because of his heart attack. Court ruled that the diving company had no special duty to the physician to prevent him from working under conditions of excess strain. Indeed, it was noted that the physician was compensated at the rate of \$200 per hour, with an additional \$100 per hour for all the time spent in the diving chamber. The diving company did pay these fees.

The court further ruled that the physician was well paid to undertake the sort of risk that caused the heart attack and that the diving company could not be held negligent for development of arteriosclerotic heart disease.

WHEN **FLU** HITS AND HURTS

HERE

Muscles
and joints

Whenever it hurts, Empirin Compound with Codeine usually provides the symptomatic relief needed.

HERE

Headache

For flu and associated respiratory infection, Empirin Compound with Codeine provides an effective bonus in addition to relief of pain and bodily comfort.

Prescribing convenience: up to 5 refills in 6 months, at your discretion (unless restricted by state law); by telephone order in many states.

Empirin Compound with Codeine No. 3, codeine phosphate* 32.4 mg. (gr. 1/2); No. 4, codeine phosphate* 64.8 mg. (gr. 1) *Warning—may be habit-forming. Each tablet contains: aspirin gr. 3 1/2, acetaminophen gr. 2 1/2, caffeine 1/2.

Burroughs Wellcome Co.
Research Triangle Park
North Carolina 27709

EMPIRIN[®] COMPOUND c CODEINE

#3, codeine phosphate* (32.4 mg.) gr. 1/2

#4, codeine phosphate* (64.8 mg.) gr. 1

IMPORTANT INFORMATION: This is a Schedule V substance by Federal law; diphenoxylate HCl is chemically related to meperidine. In case of overdosage or individual hypersensitivity, reactions similar to those after meperidine or morphine overdosage may occur; treatment is similar to that for meperidine or morphine intoxication (prolonged and careful monitoring). Respiratory depression may recur in spite of an initial response to Nalline® (nalorphine HCl) or may be evidenced as late as 30 hours after ingestion. LOMOTIL IS NOT AN INNOCUOUS DRUG AND DOSAGE RECOMMENDATIONS SHOULD BE STRICTLY ADHERED TO, ESPECIALLY IN CHILDREN THIS MEDICATION SHOULD BE KEPT OUT OF REACH OF CHILDREN.

Indications: Lomotil is effective as adjunctive therapy in the management of diarrhea.

Contraindications: In children less than 2 years, due to the decreased safety margin in younger age groups, and in patients who are jaundiced or hypersensitive to diphenoxylate HCl or atropine.

Warnings: Use with caution in young children, because of variable response, and with extreme caution in patients with cirrhosis and other advanced hepatic disease or abnormal liver function tests, because of possible hepatic coma. Diphenoxylate HCl may potentiate the action of barbiturates, tranquilizers and alcohol. In theory, the concurrent use with monoamine oxidase inhibitors could precipitate hypertensive crisis.

Usage in pregnancy: Weigh the potential benefits against possible risks before using during pregnancy, lactation or in women of childbearing age. Diphenoxylate HCl and atropine are secreted in the

breast milk of nursing mothers.

Precautions: Addiction (dependency) to diphenoxylate HCl is theoretically possible at high doses; do not exceed recommended dosages. Administer with caution to patients receiving addicting drugs known to be addiction prone or having a history of drug abuse. The subtherapeutic amount of atropine is added to discourage deliberate overdosage. Strictly observe contraindications, warnings and precautions for atropine; use with caution in children since signs of atropinism may occur even at recommended dosage.

Adverse reactions: Atropine effects include dryness of skin and mucous membranes, flushing, urinary retention. Other side effects with Lomotil include nausea, sedation, vomiting, swelling of gums, abdominal discomfort, respiratory depression, numbness of the extremities, headache, dizziness, depression, malaise, drowsiness, coma, lacrimation.

**Many
things
can cause
diarrhea.**

**LOMOTIL®
will almost
surely stop it.**

The causes of diarrhea are as varied as man's complaints and indiscretions. Because the causes of diarrhea can be obscure and because uncontrolled diarrhea can present serious problems, it is important to know a drug that will usually stop diarrhea promptly. For many physicians, the antidiarrheal drug of choice is Lomotil. It provides almost certain control of diarrhea.

It is also useful in controlling the intestinal transit time of patients with ileostomies and colostomies and the diarrhea occurring after gastric surgery.

Serious side effects are infrequent with Lomotil. It should be used with caution in young children, however, because of their variability in response. Use of Lomotil in children under two years of age is contraindicated.

**For the almost certain
control of diarrhea,**

LOMOTIL®

TABLETS/LIQUID

Each tablet and each 5 ml. of liquid contain:
Diphenoxylate hydrochloride 2.5 mg.
(Warning: may be habit forming)
Atropine sulfate 0.025 mg.

SEARLE

SEARLE & CO.
San Juan, Puerto Rico 00936

Address medical inquiries to:
G. D. Searle & Co., Medical Department
Box 5110, Chicago, Illinois 60680

1, restlessness, euphoria, pruritus, angioneu-
ema, giant urticaria and paralytic ileus.
and administration: **Lomotil is contraindi-
cated in children less than 2 years old.** Use only
liquid for children 2 to 12 years old. For
to 5 years, 4 ml. (2 mg.) t.i.d.; 5 to 8 years,
2 mg.) q.i.d.; 8 to 12 years, 4 ml. (2 mg.) 5
daily; adults, two tablets (5 mg.) t.i.d. to two
(5 mg.) q.i.d. or two regular teaspoonfuls (10
mg.) q.i.d. Maintenance dosage may be as
one fourth of the initial dosage. Make down-
age adjustment as soon as initial symptoms
controlled.
age: Keep the medication out of the reach
ren since accidental overdosage may cause
even fatal, respiratory depression. Signs of
age include flushing, lethargy or coma, hypo-
reflexes, nystagmus, pinpoint pupils, tachy-
and respiratory depression which may occur

12 to 30 hours after overdose. Evacuate stomach by
lavage, establish a patent airway and, when neces-
sary, assist respiration mechanically. Use a narcotic
antagonist in severe respiratory depression. Obser-
vation should extend over at least 48 hours.
Dosage forms: **Tablets**, 2.5 mg. of diphenoxylate
HCl with 0.025 mg. of atropine sulfate. **Liquid**, 2.5
mg. of diphenoxylate HCl and 0.025 mg. of atropine
sulfate per 5 ml. A plastic dropper calibrated in in-
crements of ½ ml. (total capacity, 2 ml.) accom-
panies each 2-oz. bottle of Lomotil liquid.

Dosage forms: **Tablets**, 2.5 mg. of diphenoxylate
HCl with 0.025 mg. of atropine sulfate. **Liquid**, 2.5
mg. of diphenoxylate HCl and 0.025 mg. of atropine
sulfate per 5 ml. A plastic dropper calibrated in in-
crements of ½ ml. (total capacity, 2 ml.) accom-
panies each 2-oz. bottle of Lomotil liquid.

Who knows what evil lurks in the mucous membranes?

Ornade[®] knows.

Each Spansule[®] (brand of sustained release capsule) contains 8 mg. of Teldrin[®] (brand of chlorpheniramine maleate); 50 mg. of phenylpropanolamine hydrochloride; and 2.5 mg. of isopropamide, as the iodide.

Knows the public's enemies — nasal congestion, runny nose, sneezing, watery eyes.

Knows what to do about them too.

All through the dark night of upper respiratory difficulty, while ordinary cold remedies wear off, the decongestant, antihistamine, and drying agent in 'Ornade' fight the never-ending battle for comfort, symptomatic relief, and free airways.

Ornade[®]. Why not let it help fight your patient's cold war.

Before prescribing, see complete prescribing information in SK&F literature or PDR.

Indications: Upper respiratory congestion and hypersecretion associated with: the common cold; acute and chronic sinusitis; vasomotor rhinitis; allergic rhinitis (hay fever, "rose fever," etc.).

Contraindications: Hypersensitivity to any component; concurrent MAO inhibitor therapy; severe hypertension; bronchial asthma; coronary artery disease; stenosing peptic ulcer; pyloroduodenal or bladder neck obstruction. Children under 6.

Warnings: Caution patients about activities requiring alertness (e.g., operating vehicles or machinery). Warn patients of possible additive effects with alcohol and other CNS depressants.

Usage in Pregnancy: In pregnancy, nursing mothers and women who might bear children, weigh potential benefits against hazards. Inhibition of lactation may occur.

Effect on PBI Determination and I¹³¹ Uptake: Isopropamide iodide may alter PBI test results and will suppress I¹³¹ uptake. Substitute thyroid tests unaffected by exogenous iodides.

Precautions: Use cautiously in persons with cardiovascular disease, glaucoma, prostatic hypertrophy, hyperthyroidism.

Adverse Reactions: Drowsiness, excessive dryness of nose, throat or mouth; nervousness; or insomnia. Also, nausea, vomiting, epigastric distress, diarrhea, rash, dizziness, weakness, chest tightness, angina pain, abdominal pain, irritability, palpitation, headache, incoordination, tremor, dysuria, difficulty in urination, thrombocytopenia, leukopenia, convulsions, hypertension, hypotension, anorexia, constipation, visual disturbances, iodine toxicity (acne, parotitis).

Supplied: Bottles of 50 capsules.

Are These Our Concern?

THIS ISSUE OF MINNESOTA MEDICINE which deals with several facets of drug abuse and the attendant dependency problems (addiction) is presented in the hope of stimulating serious physician interest and concern in the current dilemma which involves everyone.

The era of "Better Living through Chemistry" is here. We are better off because of it—if it were not for drug abuse and the attendant dependencies.

We physicians and our medical associations are an integral and important part of this complex, troublesome and puzzling situation. Some say we are central to it. Whatever our part, we cannot be indifferent or unconcerned. As members of the only legally prescribing profession we must assume responsibility to assist in its amelioration—if not its resolution.

Everyone can be certain of the following:

1. The present trend toward increasing abuse and dependency will continue unless forces are initiated to counteract it. It will not abate or disappear by wishful thinking.
2. It cannot be solved by legislation. We would do well to keep in mind Spinoza's comment: "He who attempts to determine all by law foments rather than lessens crime," Governor Rockefeller's recent proposal to the New York State Legislature notwithstanding!
3. The trend cannot be stopped by inhibiting the seller. The primary target of attention is the user—your patient or potential patient and mine.
4. Drug abusers and dependents will not be stopped by scare tactics, moralizing, viewing them as criminals or by threatening increasingly stiff penalties.

5. Solutions will be realized only when all concerned join forces in cooperative effort of analyzing, planning and programming.

If these assumptions are valid, we can do the following:

1. We can strive to be better informed and less judgmental and hasty in formulating our opinions.

Basically youth today is no different from youth at any age. Youth has always involved protest. What is different from previous generations is the overt ways of protest and the coalescing of larger segments of youth than at any previous time. Too many of us, forgetting our own protest years, are often too severe in our judgments, particularly when the use of drugs is a part of the scene. In such circumstances, the tendency is to view the individual either as a criminal or immoral which interferes with the fulfillment of our basic obligations as a physician. The explanation for such reactions may well be related to the frustrations and feelings of inadequacy we have when attempting to deal with complex problems.

2. We need to rethink our positions regarding the laws passed for control of harmful or presumed harmful drugs. We need to know that the Marihuana Tax Act of 1937 was passed by Congress only after the Federal Bureau of Narcotics had subjected the public and Congress to alarming, unfounded statements concerning the terrible consequences of its use, this despite Marijuana having been used by people of the Orient for thousands of years. The situation is so confused and out of hand today that a researcher trying to conduct a well controlled study to determine its therapeutic effects would not be permitted to try nor could

he find the necessary funds to finance it—in reality a miserable state of affairs.

3. Abuse and dependency problems include not only the psychotropic chemicals but also alcohol and tobacco. Some would add coffee and tea. In fact there is greater abuse of alcohol and more dependency problems related to it than any other drugs or combination of drugs. Needed is a better perspective on the total problem. Further, abuse and dependency problems may be more extensive and severe in age ranges beyond 30.

4. We must ask ourselves how much we contribute to abuse and chemical dependency. "Drug-stores in 1967 filled 178 million prescriptions affecting mood and behavior. The number of new prescriptions was 65 percent higher than in 1958, whereas the number of new prescriptions for all other drugs rose only 35 percent."¹

How do we explain the significant increase in the prescribing mood and behavior altering drugs in the 10 year interval? Are we prescribing as a way of handling some of our own anxieties when we cannot define a disorder? Are we not differentiating a "medical problem" from a "psycho-social problem?" "... when a physician prescribes a drug for the control or solution (or both) of personal problems of living, he does more than merely relieve the discomfort caused by the problem. He simultaneously communicates a model for an acceptable and useful way of dealing with personal and interpersonal problems."² Is this what we should be doing?

Why are nearly half of the prescriptions issued on an "as needed basis" for doses below recommended levels for effective use?³

Important to understanding and controlling drug abuse and dependency is cooperation with others, particularly the legal profession. Needed is a critical review of *all* legislation regarding drugs with a view toward revisions and improvement.

"There are endless debates over whether addicts are criminals or sick people, and whether they should go to jail or hospitals. Are the jails to take over the medical problems or must the medical profession undertake to solve the criminal problems? Should every correctional institution be forced by law to provide medical and psychological treatment facilities for addicts? Or should addicts be put in treatment facilities and never sent to jail? These questions will be adequately answered only when the medical and legal professions work together to achieve some agreement about them. But there will be no easy answers just as there have been none in the matter of alcohol abuse."⁴

Cooperation is also essential with the courts, the educators, community and governmental agencies including the legislatures.

Only by cooperative efforts with others can we be assured of any degree of success. This may be difficult because we physicians have not been very successful cooperators in the past. In my opinion it would be worth a try!

How Can We Help?

DR. JOSEPH H. BRENNER* has said that the handling of the drug situation in our society is too serious and too difficult to be entrusted to politicians, and he has suggested that what we need now are people more directly concerned with individual welfare—physicians, for example—to become interested and knowledgeable in this field. In that connection, he goes on to say:

*Medical Department, Massachusetts Institute of Technology; Director, Cambridgeport Medical Clinic, Cambridge, Massachusetts.

"Despite many assertions to the contrary, a vast amount is known about the various drugs that are illicitly used, and especially about marihuana. To suggest that the gaps in our knowledge of the effects of marihuana are so great as to paralyze our ability to formulate reasonable policies governing prescription and/or proscription of its use, is to allow free rein to all those who advocate the attachment of severe penalties to the use of marihuana."¹

Just to mention the possibility of seriously con-

considering legalization of marijuana is to risk alienating many of our colleagues, who associate that idea with radicals and far-out freaks. So it seems appropriate to quote briefly from William F. Buckley, editor of *NATIONAL REVIEW* and one of the United States' best-known conservatives, on his subject:

"Our responsibility is to move ahead of public opinion: indeed to influence public opinion. Mr. Cowan² insists quite simply that there are no arguments, of any force or gravity, by which to justify the treatment routinely given to people who

use marijuana here and there in the United States. I flatly agree with him."³

If, as Mr. Buckley suggests, it is the responsibility of conservatives to move ahead of public opinion, how much greater is it our responsibility, as physicians, in this medically-related matter, to move ahead of and to influence public opinion? At best, to say we don't yet know enough is a weak (and inaccurate) excuse; at worst, it is a shameful "cop-out." The community to whose welfare we are dedicated deserves better than that.

On Words Not Found in Dictionaries

THE EDITORIAL BOARD of this Journal has a flexible neological policy. It is unlikely that many new words not dignified by an entry in one or the other of the great English dictionaries* will enter the language through these pages. Ours is a cautious and conservative Board which wants to be sure before launching a neologism that (1) no known word in the English language will express the idea and nuances of the new word and (2) that there is a new idea or thought requiring expression. We will not be so reactionary as to deny authors their right to accouchement of a literary baby if their infant word can qualify. Unfortunately very few can meet these simple standards. But we are not arguing for zero population growth of dictionary entries. The Oxford English Dictionary has just brought out (at \$50.00) a supplement of 1331 pages of new words added to the language since 1933. Of course, this is just A-G with two more volumes to come. One might plaintively say the language is full of words already and advise authors to use the well known and understood ones before resorting to new coinage. The newly

coined word might well be counterfeit not equal in value to the old expression.

These remarks are intended to apply to the written word used in context and not to a glossary such as addiet's language published elsewhere in *MINNESOTA MEDICINE*.[†] It is evident that some of these words are designed not to express a new thought but to conceal it. The "pusher" does not hawk his wares on the street corner: "Heroin for sale here"; but whispers hoarsely, "Horse."

The argot of the socially unacceptable, of thieves, whores, prisoners, and "junkies" is designed more for obfuscation than revelation. As the word is understood by the "squares," "fuzz," "nares" etc. new expressions appear, thus "deek," "dope," "hit," "junk," "stag," "smack" and many others, all meaning heroin. Some of these will remain in the language.

We must distinguish between the new word intended for camouflage that will die when its cover is blown, and the word that expresses a new idea which has a place in the changing language.

Reuben Berman, M.D.
Editor

Chemical Dependency

THERE WAS A time when the term "chemical dependency" described a phenomenon which was considered by the general population to be rela-

tively insignificant, unimportant, perhaps a rarity. The term may have evoked visions of an Asian opium den, or the South American Indian driving

his body by chewing coca leaves; or a pariah, possibly a musician, in New York City. A generation ago drug dependency seemed remote. In the last decade, this has changed. Chemical dependency is now seen pervading all levels of society, here and elsewhere.

Clearly, there has been a massive increase in the use of chemicals to alter the state of consciousness of the user. It is also probable that there has been an increased willingness by many users to experiment with various chemicals to produce a change in thinking or feeling. But in addition to the actual increase in drug use, there may also be an increasing awareness that chemical dependency is not confined to foreigners, outcasts, and youth, but that chemical dependency may also exist in the person who uses alcoholic beverages, hypnotics, tranquilizers, stimulants, appetite suppressants, or analgesic drugs in certain ways. Chemical dependency is a broader concept

than the term it is supplanting, drug addiction, and chemical dependency affects many persons who never considered themselves to be drug dependent.

Physicians have traditionally been interested in the effect of chemicals upon the human body. Pharmacology and toxicology have long been part of the basic medical science curriculum. The rapidly burgeoning number of chemicals of abuse which are being used have resulted in the situation in which a physician finds it difficult to remain abreast of developments in this area. The members of the Subcommittee on Alcoholism and Drug Abuse of the Committee on Mental Health of the Minnesota State Medical Association are very pleased that this issue of MINNESOTA MEDICINE is being devoted to papers dealing with aspects of chemical dependency.

Alcoholism and Drug Abuse

Pregnancy

THE USE OF DRUGS in pregnancy has become of great concern with some of the teratogenic crises that have occurred in recent years.

Current information available indicates that with few exceptions every drug given the mother reaches the fetus regardless of the stage of gestation at which it is administered. It has also been proven that the specific effect of any drug on the fetus is dependent on the stage of fetal development at the time it is given to the mother. The most dangerous time for drug administration is the first trimester of pregnancy during which organ and limb formation and development occurs.

Recent data would show the drugs used for therapeutic purposes in pregnancy may cause late effects on the offspring. The data concerning the

development of adenocarcinoma of the vagina in girls in their teens and early twenties whose mothers were treated with stilbestrol and other estrogens during pregnancy to prevent abortions is very suggestive of a cause and effect relationship.

Therapeutic nihilism is not popular but the very conservative use of medications during gestation is the only way to avoid both short and long range dangers to the fetus.

In the period of greatest danger many women are not even certain they are pregnant. It therefore behooves all physicians dealing with female patients in the reproductive age group (age 13-45) to take a menstrual history before prescribing medication if injury to the fetus at the time of its greatest susceptibility is to be avoided.

OLD DOC HESS SAYS: Distorted, askewed, unreliable figures, expressed by a famous name, too often are repeated as a reliable fact. . . . C.O.R.

The Physician and Public Opinion Concerning Drug Addiction

IT IS REFRESHING to find a lawyer performing a careful study of the history of laws regarding the use of drugs in the United States. The paper in this issue entitled "A Lawyer's Autopsy On Our Dead Drug Laws" by James P. Cullen,* provides a background for serious criticism of the current situation with regard to the entire problem. No physician doubts that drug addiction is a serious medical matter and that much harm is done by virtue of the fact that many persons do become addicted to one or another pharmacologic agent. As the author of this paper points out, purported remedies can oftentimes be worse than diseases.

There are many reasons for opposing the acceptance of currently accepted dogma concerning the best way to control the improper use of drugs of various sorts, including especially psychotropic drugs. Actually, the most serious social problem in connection with addiction to psychotropic drugs is related to our current method of attempting to control their use by forcing addicts to pay exorbitant prices from illicit dealers to meet the problems of their drug dependency. Our society has in effect driven addicts into violent crime to obtain the wherewithal to satisfy their acquired drives. It is generally conceded that at least half of the felonies committed in our larger cities are related to this phenomenon.

Even with respect to the more innocuous agents such as marihuana, the fact that it cannot be purchased except illegally, and because in many states possession and/or use are treated as felonies, persons addicted to the use of this deceptive weed also find themselves associated with the criminal underworld and become part of the criminal culture that is eroding civil tranquility.

Drug addiction is a disease. As such it should be treated by physicians not policemen, except when addicts commit overt acts against persons or property. The medical profession has turned its back on its responsibilities to public education in the matter. As a result, harsh criminal penalties for possession and use of psychotropic drugs have been enacted into law by state legislatures, sometimes on voice votes, and by the Congress, with less than proper consideration of the totality of the problems involved. There is still in the late

twentieth century American society a childlike belief that more stringent police measures can control addiction. The 1970 Drug Control Act properly sets up penalties for the illicit manufacture and sale of dangerous drugs, but it still leaves the addict in the category of a criminal. As Cullen points out, the Act also introduces legal authorization for invasion of privacy, such as "no-knock" entry, which could be readily abused.

It is not as though there are no models for better mechanisms for control in the world. The British system, in which the physician does have responsibility has proven to be vastly superior to the current American plan for control of improper use of psychotropic drugs.

A great many young people have become involved in the use of marihuana. By making such use a felony or even a misdemeanor, we have brought thousands, in the aggregate undoubtedly hundreds of thousands of our young people into the criminal subculture of our society and have destroyed many lives. There is an ethical problem here for society as a whole but especially for physicians who have not insisted upon dealing with drug dependency as a medical rather than a law enforcement problem.

There has recently been published a perceptive essay on this subject by Mervyn and Deborah Silverman¹ which deals with the ethical responsibilities of physicians in relation to problems of drug abuse. Dr. Mervyn Silverman is Director of the Office for Consumer Affairs of the Food and Drug Administration of the U.S. Department of Health Education and Welfare. The Silvermans say: "We need to realize that eradication is an unrealistic goal, so that we can settle down to a constructive, long-term solution. Society, like the drug abuser, must stop believing in the magic of any single cure for its problems, and institute a sane complex of effective measures. Any action in the name of moral values is empty principle if it is not based on the facts. . . . We need new facts, strong pressure groups from the ranks of concerned professionals, and education of public opinion."

No ethically acceptable solution of the drug addiction problem can occur unless and until physicians accept their own moral responsibilities

*See page 223.

to their patients and to society, in public education and in promoting research on methods of medical management. No disease is destroying more young lives today than is drug dependency. It is a major challenge to the medical profession to bring sanity

into the public dialogue that will determine political action in this field. The American medical profession has for too long closed its eyes to the entire problem.

New Drugs in Pregnancy

LITTLE IS KNOWN about the effect of most drugs on human pregnancy. Those that have definite adverse effects such as thalidomide are fortunately rare. With few exceptions, manufacturers tell us that a drug's effect on human pregnancy is not known and should be used only when its beneficial effects overbalance its hazards (which we have already been informed are unknown). When will these effects be known? Probably not early in the history of the marketing of new drugs since rarely is it adequately pretested on the pregnant woman.

In the absence of facts, avoidance is an excellent alternative. Mandatory medication in pregnancy is unusual. Patients, as well as physicians,

are concerned about a drug's effect when pregnancy is known and should be encouraged to use drugs less frequently during this time.

The most dangerous period is in the first eight weeks, when pregnancy is often unsuspected, unfortunately by the physician as well as the patient. For purposes of drug control a menstruating female should be assumed pregnant until proven otherwise.

When prescribing medication, a preliminary question is always, "Do you have any drug allergies?" Might not the next question be, "Are you pregnant or might you be in the near future?"

Cover Sculpture

"Bayanihan"

"Bayanihan" is Tagalog and translated means "working together." Dr. Donald L. Carlon, a radiologist in Moorhead, has been doing both welded and cast metal sculpturing for approximately four years. The cover sculpture is 21 inches high and is a lost wax, bronze casting. He told the editors that the subject is an exercise of the human body in relationship to itself.

Dr. Carlon is a graduate of Syracuse University Medical School in New York and did his postgraduate work at the Mayo Clinic.

Adolescent Medicine

February Issue

Many of the articles published in the February issue of MINNESOTA MEDICINE were presented at the Second Annual Medical Seminar of the West Bank Medical Center (Fairview Hospital and St. Mary's Hospital) in Minneapolis, April 15, 1972.

First Do No Harm

"One must question whether physicians, who are most likely to have positions of leadership in directing professional drug abuse rehabilitation programs, are adequately trained for the tasks of diagnosis and coordination of delivery of diversified services."

THIS QUOTATION is from a recent article* reporting on a survey of medical schools in the United States. The study was "devised to explore whether schools training future physicians, nurses, pharmacists, psychologists, social workers and lawyers were providing training resources that are needed to effectively change the life styles of drug abusers." In commenting on the success of medical schools in this regard, the authors stated that ". . . Medical students are most often trained in the pharmacological and medical facets of this condition [drug abuse]. The drug abuser's psyche is taught about less often and legal issues are covered least of all. *It would appear that the future physician is at best, only prepared to handle bodies affected by drugs with the aid of other drugs.*"

Nearly two out of three medical schools responded to this study with more than 80% indicating that drug abuse is part of their course curriculum. It would seem that medical students are, for the most part, receiving some training in drug abuse.

It is not by accident, however, that an entire alternative health care delivery system, in the form of half-way houses and drop in/crisis intervention centers, has developed to fill the void left by the medical profession. The public is telling the medical profession that the physician and his methods are inadequate to meet the needs of the drug abuser. This loss of confidence in physicians to deal competently with problems of drug abuse leads to a loss of confidence in other areas of health care. The physician and physician-in-training have a responsibility to establish competent, helpful, health service systems to deal with drug abuse rehabilitation and prevention or at the very least to cooperate with and aid the alternative delivery systems which have, out of necessity, developed.

The problem of drug abuse is a multi-faceted one encompassing medical, legal, pharmacological and sociological considerations. In devising a curricular solution, therefore, one must incorporate multi-disciplinary principles.

At the University of Minnesota, a course in "Drugs and Society" is offered at the College of Pharmacy. The course, which incorporates principles of psychology, sociology, medicine, law, communication, education and pharmacology, is offered to all of the health science students at the University. It includes guest lecturers and field experiences. It fosters a team approach, enabling students from diverse backgrounds to work together toward the solution of societal problems. Out of the 160 students taking the courses this quarter, from the schools of medicine, law, nursing, pharmacy, occupational therapy, physical therapy, psychology, sociology, public health, hospital administration and social work (with no more than 18% representation from any one discipline) —medical students account for less than 3% of the registrants, although the course is an approved elective in the medical school. The remaining medical students are receiving their "training" in drug abuse in a few hours in their pharmacology and community practice sequence, isolated from other disciplines.

The answer is *not* to offer a required medical school course in drug abuse, since that would defeat the interdisciplinary environment even if the multi-disciplinary presentation of material could be mimicked. The answer, if the medical profession is to meet its responsibilities to the public through the training of medical students, is to cooperate with the other disciplines at the University by actively encouraging the medical student to get involved in the prevention and treatment of what a recent Gallup Poll indicates is the third greatest problem our country faces today and perhaps, if necessary, offer a supplementary medical component for medical students.

Letters to the Editor

In the August 30, 1972 Memorandum, "To All Members of the Medical Staff," from the Chief of the Medical Department and the Director of Medical Education, "Bureaucratese" took over as an attempt was made to announce, "A Nurse Utilization: Patient Care Systems Project," describing the "IDEALS methodology" and the "Use of multidiscipline approach in designing the systems" as it pertains to "the patient outward." ". . . virtually every area of the health care field involved themselves in the design of the patient care systems;" and the "interrelated systems" which were "fully designed and implemented" as could be found in the "Nursing Outlook, Vol. 4, No. 2." I guess that means that we are going to be given a course on how to take care of patients.

This reminds me of an occasion at the time of World War II when a layman, neighbor of mine, asked me if I would serve on the Emergency Care Units. I promptly agreed, but was then instructed that it would be necessary for me to take the course in Bandaging, Pressure Points for Massive Bleeding, Resuscitation Methods, etc., etc., and if I passed the course I would be approved. I thanked him, but I did not offer to take the course and presumably flunked the preliminary as I never again heard of it. So when I see that our own Metropolitan Medical Center is having a Conference which was scheduled for September 14, teaching us how to take care of patients, "with total clinical responsibility . . ., structuring . . ., collecting . . ., interpreting . . ., and documenting of patient information," then I feel like saying, "Well, thank you, if you need any professional assistance, let me know."

Carl O. Rice, M.D., Ph.D.
Editor Emeritus

It was interesting to read Dr. Reece's laboratory letter in the November* issue of MINNESOTA MEDICINE.

Additionally thinking of brain sources of elevated CPK—Alzheimer's disease also causes elevation of CPK.

The hypothyroidism elevation caused us a degree of concern a few years ago, before we realized that this elevation was due to the hypothyroidism.

Chas. M. Bagley, M.D.
Duluth, Minnesota

*Page 1046.

I enjoyed Dr. Reece's laboratory letter* in the November MINNESOTA MEDICINE but I feel you missed an opportunity to make a point with regard to correcting creatinine clearance values for body surface area.

I feel that it is a point well worth stressing that the clearance values can only be adequately interpreted in respect to the correction for a body surface area and that simple numerical value in itself cannot be adequately interpreted unless correction is stated or the units given.

It is a small point, but I think it is deserving of emphasis.

John M. Burns, M.D.
St. Paul, Minnesota

I think that there can be a very great distinction between generic drugs and brand name drugs. And that applies to products of original research that have outlived their patent protection as well as to drugs that have long been in the public domain. Let me explain why.

The Importance of the Manufacturing Environment

In terms of formulation, quality control, and the ability to reproduce an essentially identical product, batch after batch, I doubt that many firms are properly equipped to put out a product that is as carefully controlled as the product marketed by a pharmaceutical company with sophisticated research and high quality manufacturing facilities. For example, when a company comes out with its own preparation of a drug that has just lost its patent protection, there is no assurance that the drug it produces will be a therapeutic equivalent. The raw material could be identical and yet bioavailability might vary from complete unavailability to that which is equivalent to the original.

It Isn't Enough to Meet USP and NF Standards

Meeting USP and NF standards is not enough to guarantee therapeutic equivalence. In certain instances, stricter standards must be applied. Right now, the New York Heart Association has a committee that is studying the problem of digoxin equivalent-

lency. I am certain that they are going to recommend a bioavailability assay of a particular digoxin. Unless this is done, they will not recommend it for purchase or use in New York City hospitals. It represents too much of a hazard. They have gone so far as to recommend a batch-by-batch certification of bioavailability even though the company has been reproducing and marketing a digoxin product through the years.

The Problem of Controlling Bioavailability of Generics

The FDA does not have the manpower to inspect the quality control capabilities of hundreds of houses specializing in generic products. And I don't think that the average pharmacist is knowledgeable or aware of the quality and bioavailability of the infinite numbers of generic preparations. A recommendation has been made that every time a generic house (or for that matter a large pharmaceutical company) markets an already existing drug for the first time, a modified new drug application should be submitted. The manufacturer would have to show that his compound is the therapeutic equivalent of the standard compound in use, assuming that the standard compound is one that has been available for an extended period—say 15 years. This would be one indication that the control of bioavailability is beginning to get the attention that it deserves.

Clinical Predictability More Important Than Price

Although the question of price has been greatly exaggerated, it is true that patients can often save money on generic drugs. But you are going to dare attempt to save money if it jeopardizes patient's health. Let us turn to the example of cardiac glycosides. In recent years, these drugs are probably the most common drugs we use with respect to the small difference between a maximally effective dose and a toxic dose. If you are dealing with a drug of this type, the physician's concern must be clinical predictability. At the time of variations in bioavailability, it would be sheer folly to try to save the patient what might amount to maybe \$10 or \$20. The physician cannot afford to age his patient unless he is sure that the drug prescribed has the same positive effect each time the prescription is renewed. This is especially significant when the patient is on the product, not for himself but for the rest of his family.

minimize nonequivalence of drug components produced by different manufacturers. Arguments relate largely to the extent of product inequivalences. Experience over the past six years has uncovered a greater incidence of nonequivalence of products prepared by different manufacturers from generically equivalent substances than many had previously surmised.

Newer Bioavailability Studies Reveal Differences

though equivalence of ent preparations of a substance may be de- by certain physical, cal or biological char- actistics, identity is not assured even though characteristics may scribed in compendia as the USP, NF or de- l by other specific e standards. More- even with equivalent substances, similar maceutical products e produced by differ- manufacturers such these products are bio- ally or therapeutically ivalent.

Growing Awareness of Potential for Nonequivalence

experience increases drug substances de- from different sources under different condi- , it should be possible blish specifications in icient detail to minimize potential for their non- valence. However, e is general agreement product therapeutic valence would still not ssured even if one could

Bioavailability may be defined as a measure of the rate and amount of absorption of a drug substance from its administered dosage form. For several years pharmaceutical scientists have proposed that bioavailability data on presumably equivalent dosage forms provide the best measure of product equivalence—short of adequate clinical trial. In their continued search for shortcuts to the evaluation of product equivalence, medical and pharmaceutical scientists have increasingly relied upon bioavailability characteristics as reflected by blood levels of a drug after its administration to human subjects.

Leading manufacturers now conduct comparative bioavailability studies on their own product dosage forms after production process changes that would have been considered inconsequential a few years ago. This isn't surprising, since there are so many possible differences in production operations that the opportunities for inequa-

lent generic and brand name products are numerous—even when the production process begins with identical chemical substances. Moreover, reputable manufacturers are striving to improve *in vitro* control measures, such as dissolution characteristics, which are being related more meaningfully to bioavailability reference data.

As a result of advances in scientific instrumentation and analytical methodology which permit measurements of small quantities of drug substances in the body, our abilities to detect differences in bioavailability and possible therapeutic nonequivalence have appreciably improved.

Product Selection

Based on Patient Response

Improved specifications and standards can better assure the equivalence of drug substances. Manufacturers, compendia and regulatory agencies can all play a part. However, it is the drug product, not the drug substance, that the physician, pharmacist, nurse and patient-customer utilize. How can these indi-

viduals make or influence specific product selections to minimize variations in therapeutic equivalence of multisource drugs? Patients' responses to a drug product provide a basis of experience to aid the physician in his selection of a particular product. The nurse and pharmacist can also help detect patient responses, but ultimate responsibility must remain with the physician.

Reputation of Manufacturer as Basis for Product Selection

The physician, to assure that his patients receive quality health care, must rely upon the capabilities of the reputable pharmaceutical manufacturer who is equipped to develop, prepare and control a quality product of uniform, reliable therapeutic performance. Substitution with purportedly equivalent generic products that are only superficially evaluated by an imitator manufacturer can place the health of the patient secondary to factors of price or convenience for the provider.

Opinion & Dialogue

What is your opinion, doctor?
We would welcome your comments.

1155 Fifteenth Street, N.W., Washington, D.C. 20005

MINOCIN[®] made the difference in just eight days.*

Clinical Data:

Patient: 47-year-old male.

Diagnosis: Severe pyoderma, left hand.

Culture: *Staphylococcus aureus*, coagulase positive and sensitive to MINOCIN.

Temperature: 102° F

Therapy: MINOCIN Minocycline HCl Capsules, 100 mg: 200 mg *stat*, 100 mg every 12 hours. Medication began 9/7/71. By fourth day, temperature was normal and pustular lesions considerably improved. Last dose taken 9/14/71.

Concomitant therapy: None.†

Semisynthetic

MINOCIN[®]
MINOCYCLINE HCl

Capsules, 100 mg: 2 *stat*, 1 q 12 h.

Indications: For the treatment of susceptible infections; e.g., *E. coli*, *D. pneumoniae*. For full list of approved indications consult labeling.

Contraindications: Hypersensitivity to any tetracycline.

Warnings: The use of tetracyclines during tooth development (last half of pregnancy, infancy and childhood to the age of 8 years) may cause permanent discoloration of the teeth (yellow-gray-brown). This is more common during long-term use but has been observed following repeated short-term courses. Enamel hypoplasia has also been reported. Tetracyclines, therefore, should not be used in this age group unless other drugs are not likely to be effective or are contraindicated. In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, use lower total doses, and, in prolonged therapy, determine serum levels. Photosensitivity manifested by an exaggerated sunburn reaction has also been observed in some individuals taking tetracyclines. Advise patients apt to be exposed to direct sunlight or ultraviolet light that such reaction can occur, and discontinue treatment at first evidence of skin erythema. Studies to date indicate that photosensitivity does not occur with MINOCIN Minocycline HCl. In patients with significantly impaired renal function, the antianabolic action of tetracycline may cause an increase in BUN, leading to azotemia, hyperphosphatemia, and acidosis. CNS side effects (lightheadedness, dizziness, vertigo) have been reported, may disappear during therapy, and always disappear rapidly when drug is discontinued. Caution patients who experience these symptoms about driving vehicles or using hazardous machinery while taking this drug. **Pregnancy:** In animal studies, tetracyclines cross the placenta, are found in fetal tissues, and can have toxic effects on the developing fetus (often related to retardation of skeletal development). Embryotoxicity has been noted in animals treated early in pregnancy. Safety of use during human pregnancy has not been established. **Newborns, infants and children:** All tetracyclines form a stable calcium complex in any bone-forming tissue. Prematures, given oral doses of 25 mg./kg. every 6 hours, demonstrated a decrease

in fibula growth rate, reversible when drug was discontinued. Tetracyclines are present in the milk of lactating women who are taking a drug of this class.

Precautions: Use may result in overgrowth of nonsusceptible organisms, including fungi. If superinfection occurs, institute appropriate therapy. In venereal diseases when coexistent syphilis is suspected, darkfield examination should be done before treatment is started and blood serology repeated monthly for at least four months. Because tetracyclines have been shown to depress plasma prothrombin activity, patients on anticoagulant therapy may require downward adjustment of such dosage. Test for organ system dysfunction (e.g., renal, hepatic and hemopoietic) in long-term use. Treat all Group A beta hemolytic streptococcal infections for at least 10 days. Avoid giving tetracycline in conjunction with penicillin.

Adverse Reaction: GI: (with both oral and parenteral use): anorexia, nausea, vomiting, diarrhea, glossitis, dysphagia, enterocolitis, inflammatory lesions (with monilial overgrowth) in anogenital region. **Skin:** maculopapular and erythematous rashes. Exfoliative dermatitis (uncommon). Photosensitivity is discussed above ("Warnings"). **Renal toxicity:** rise in BUN, dose-related (see "Warnings"). **Hypersensitivity reactions:** urticaria, angioneurotic edema, anaphylaxis, anaphylactoid purpura, pericarditis, exacerbation of systemic lupus erythematosus. In young infants, bulging fontanels have been reported following full therapeutic dosage, disappearing rapidly when drug was discontinued. **Blood:** hemolytic anemia, thrombocytopenia, neutropenia, eosinophilia. **CNS:** (see "Warnings.") When given in high doses, tetracyclines may produce brown-black microscopic discoloration of thyroid glands; no abnormalities of thyroid function studies are known to occur.

NOTE: Concomitant therapy: Antacids containing aluminum, calcium, or magnesium impair absorption; do not give to patients taking oral minocycline. Studies to date indicate that absorption of MINOCIN is not notably influenced by foods and dairy products.

*Indicated in infections due to susceptible organisms. Culture and sensitivity testing recommended. Tetracyclines are not the drugs of choice in the treatment of any staphylococcal infection.

A Lawyer's Autopsy on Our Dead Drug Laws

JAMES P. CULLEN, J.D.*

ON OCTOBER 27, 1970, the Comprehensive Drug Abuse Prevention and Control Act,¹ was officially approved. Passage of this sweeping piece of legislation represented not only an attempt to codify in one package a hodgepodge of federal laws purporting to regulate the manufacture, distribution, sale, and possession of dangerous drugs, but also a shift in Congressional attitude toward the role of law insofar as it regulates drug "abuse".

The new federal drug control law is noteworthy for a number of reasons:

1. Its introduction of the novel concept of scheduling "controlled substances" in accordance with certain recited findings² and punishing their unlawful sale or distribution on the basis of the schedule in which they are included. This approach is markedly different from the past legislative practice of terming and defining most dangerous drugs as "narcotics" despite, and in apparent ignorance of, their gross pharmacological and medical differences.

2. The shift in emphasis with regard to penalizing possession offenses. Under prior law possession offenses were barely distinguishable from sale offenses with respect to the severity of penalties which could be imposed upon conviction.

The new drug law contains a clear mandate to federal law enforcement authorities to concentrate their efforts on unlawful manufacture, sale or dis-

tribution offenses. In addition to the requirements that unlawful possession be both "knowingly and intentionally", the Congress has seen fit to limit the maximum penalty upon the first offense conviction for unlawful possession of *any* controlled substance to a maximum sentence of one year imprisonment or a \$5,000 fine or both. The maximum sentence which may be imposed upon conviction of second and subsequent offenses of unlawful possession is two years imprisonment or a \$10,000 fine or both.³

3. Specific provisions of the Act now make it possible for an offender to be placed on probation in lieu of the court entering a judgment of guilty and further, if he qualifies, to obtain an expungement of all recordation relating to his arrest, indictment or information, trial, finding of guilty and dismissal and discharge.⁴

4. The re-emphasis and strengthening of the quota system insofar as it applies to the manufacture of dependency producing and otherwise dangerous substances. This is in part achieved through the requirement of more detailed reporting.⁵ It is further achieved by the Attorney General's determination and setting of manufacturing quotas and the granting of limited authorizations for drug manufacture.⁶ The availability and use of "administrative inspection warrants"⁷ substantially

*Associate Professor of Law, University of Minnesota, Minneapolis.

1. 84 Stat. 1236, 21 U.S.C. §801 (1970).

2. 84 Stat. 1247, 21 U.S.C. §812 (1970).

3. 84 Stat. 1264, 21 U.S.C. §844 (1970). There is an exception to the limited sentence approach if the defendant is found to be a "dangerous special drug offender". In that instance a defendant can be sentenced for an "appropriate term not to exceed twenty five years." 84 Stat. 1267, 21 U.S.C. §849 (1970).

4. 84 Stat. 1264, 21 U.S.C. §844 (b). The expungement privilege is extended to those who were not over twenty-one years of age at the time of the offense. Query: is the spirit of misadventure limited to the young? If answered in the negative, is this not an arbitrary classification in violation of the due process clause of the 5th Amendment? See *Shapiro v. Thompson*, 394 U.S. 618 (1969), and *Bolling v. Sharpe*, 347 U.S. 497 (1954) which indicate that the right to due process under the fifth amendment includes within its guarantee the principle of equal protection.

5. 84 Stat. 1258, 21 U.S.C. §827 (1970).

6. 84 Stat. 1257, 21 U.S.C. §306 (1970). It should be noted that the power of the Attorney General to establish production quotas is limited to those substances included in Schedules I and II. Only recently methamphetamine (speed) was moved from Schedule III to Schedule II, ostensibly for the purpose of subjecting this substance and its manufacturers to the quota provisions of the law.

7. 84 Stat. 1274, 21 U.S.C. §880 (1970). These warrants are issued on the basis of "probable cause" which "[m]eans a valid public interest in the effective enforcement of this title or regulation thereunder sufficient to justify administrative inspections of the area, premises, building or conveyance or contents thereof, in the circumstances specified in the application for the warrant." 84 Stat. 1275, 21 U.S.C. §880 (d) (1) (1970).

strengthens this quota and authorization scheme. Needless to say the illicit manufacture or distribution of dangerous drugs ought to be treated from a criminal standpoint in as punitive a fashion, if not more, as their sale on the street corner. It is only recently, however, that federal law enforcement authorities have begun to "crack down" by arrest or indictment.⁸

5. The establishment of a Commission on Marihuana and Drug Abuse.⁹ This Commission, whose membership consists of two members of the Senate, two members of the House of Representatives and nine members appointed by the President of the United States, represents an apparently sincere attempt on the part of the Congress to inform itself on the subject. Not so clear, however, is the weight which will be given to this Commission's reports and proposals for legislative action.

There are several other provisions of the new drug act deserving of professional attention. Noteworthy among these are the shift from the taxing power to the interstate commerce power as the constitutional basis for this drug legislation,¹⁰ the increase in funds made available to mental health centers and similar institutions for the purpose of treating those with "drug dependency" problems as well as those with opiate addiction problems¹¹ and the granting of important powers to the Secretary of Health Education and Welfare.¹²

On the other hand, a pervasive examination of the new act discloses numerous deficiencies. Notable among them are provisions authorizing the issuance of "no knock" search warrants,¹³ sum-

mary forfeitures of property,¹⁴ and the preferential treatment accorded a manufacturer who has exceeded his production quota or has engaged in the manufacture of an unauthorized substance.¹⁵ The inclusion of marihuana in Schedule I, which includes such drugs as heroin and cocaine, and the complete absence of any regulation of either ethyl alcohol or nicotine creates further cause for concern.

Considering the above points of controversy together with the obvious fact that our criminal justice system continues under present law to be the modality into which most drug offenders are channeled by society, one might well hesitate before opining on the value of this legislation as a reform measure. It is this author's opinion, however, that the new federal act has much to be said for it, not only because of its desirable substantive reforms, but also because of the spirit in which it was enacted.

It can be fairly concluded that passage of the Controlled Substances Act was an attempt by Congress to legislate away from the failure and pitfalls of prior law. Indeed this legislative action can be viewed as an endeavor to inject some credibility into a milieu replete with falsehood and credibility gaps. The simple requirement, for example, that before a substance may be lawfully controlled by the Attorney General there must be "substantial evidence of potential for abuse", coupled with the research and study aspects of the Act, would seem to hold some promise for mean-

8. On January 18, 1972, federal officials announced the seizure of 1 million amphetamine pills worth approximately 1.5 million dollars. These pills had been exported to Mexico by the Strassenburgh prescription products division of the Pennwalt Corp. and then smuggled back into the United States. Eighty persons were arrested by the Bureau of Narcotics and Dangerous Drugs as a direct result of their ten month investigation of this particular problem. Minneapolis Star, Jan. 18, 1972, at 2A, col. 1.

9. 84 Stat. 1280, 21 U.S.C. n. at §801 (1970).

10. See 84 Stat. 1242, 21 U.S.C. §801 (3)-(6) (1970). It is made very clear that "Federal Control of the intrastate incidents of the traffic in controlled substances is essential to the effective control of the interstate incidents of such traffic." 21 U.S.C. §801 (6).

11. 84 Stat. 1239, 42 U.S.C. §2688n-1 (1970).

12. For example, the recommendations of the Secretary of Health, Education and Welfare regarding scientific and medical matters and whether a particular substance should be legally controlled are binding on the Attorney General. 84 Stat. 1246, 21 U.S.C. §811 (b) (1970).

13. 84 Stat. 1274, 21 U.S.C. §879 (b) (1970). The U.S. Supreme Court decision in *Ker v. California*, 374 U.S. 23 (1963), upholding a conviction for possession of narcotics was a weak adoption of the rule that "exigent circumstance" will justify an officer in failing to announce his authority and purpose before entering a residence. The language contained in the cited No-knock Statute is a paraphrasing of the exigent circumstances rule enunciated in *Ker*. See also *State v. Parker*, 283 Minn. 127, 166 N.W. 2d 347 (1969), which is the general authority for No-Knock search and seizures in Minnesota.

14. 84 Stat. 1276, 21 U.S.C. §881 (1970). Among the property subject to forfeiture is "[V]ehicles . . . which are used . . . to transport or in any manner to facilitate the transportation, sale, receipt, possession or concealment . . ." of controlled substances. 84 Stat. 1276, 21 U.S.C. §881 (a) (4) (1970). Under this provision one transporting or possessing a joint of marihuana in the glove compartment of his automobile faces potential seizure and forfeiture of that vehicle. Query as to whether or not such forfeitures constitute excessive fines in view of the fact that they are in addition to any fine or imprisonment which may be levied or imposed upon conviction of the underlying offense. If so then the Eighth Amendment may have some vitality in this area of controversy.

15. See 84 Stat. 1262, 21 U.S.C. §842 (c) (1970). Such offenses are subject to a "civil penalty" of not more than \$25,000 unless "knowingly" committed, in which case it is possible that the offender (if he can be identified) may be sentenced to imprisonment for not more than one year or a fine of not more than \$25,000, or both. This "light" penalty is a good example of an unwarranted legislative distinction between "white collar" crime and that committed by others.

ful remedial legislation in the near future. I attend myself on this point because such an approach, from a governmental standpoint, of educating oneself prior to legislating dramatically stands apart from the conduct, attitude and approach of governmental officials in the past. Unfortunately the general public, due to their own ignorance on the subject, is quite incapable of appreciating this fact—and, I submit, physicians and lawyers as well.

The respect to which any law is entitled from the public depends on a variety of factors. The fairness or "morality"¹⁶ of a given law is important, particularly with respect to criminal laws and the conduct they proscribe. Due consideration must be given to insuring that application of a law will not violate fundamental and constitutional rights of individuals. Certainly the efficacy of a law in securing its desired objectives provides a further standard with which to pass judgment on the value of a given legal command or restraint. There are other considerations—suffice it to say, however, that the process by which a law is developed is a fundamental and perhaps the threshold point for evaluating and insuring its fairness and validity. So it is that our legislative process and the legislators themselves are of such extreme importance to a just society.

Changeable as they may be through the democratic process of bills, committee hearings, debates and votes, most laws (criminal laws in particular) represent a divining by a few powerful individuals as to what is good or bad for society. Powerful and influential interests have long been able to steer civil legislation through the Congress to ultimate passage—all despite the presence of ulterior motives in doing so. It should be no surprise then to discover that our criminal laws have been enacted in a similar vein. Nowhere is this proposition more clear than in the area of legal drug control and enforcement.

How questionable drug legislation became enacted into law and why such laws have been allowed to stand despite the adverse effects they

have had on our society and its rule of law are not merely rhetorical questions. Indeed the answers to these questions and the insight they provide may be of assistance to both the legal and medical professionals. Thus it is that this writing is intended to provide the reader with an overview and analysis of only recently repealed or amended drug control laws, and to place controversial facts into their proper historical perspective. It is too much to hope that hardened opinions will be changed or modified but this writing may help to bridge the gap of misunderstanding which lies between embanked positions on the subject of legal drug control.

Overview of Prior Narcotic and Soft Drug Legislation

In retracing the development of drug control legislation¹⁷ in the United States, one might well begin with the Civil War for it was immediately prior thereto that our "drug problem" took root.

The invention of the hypodermic syringe in 1853 was a technological advance which enabled soldiers on both sides of the conflict to administer morphine for the relief of pain from battlefield wounds and dysentery. Addiction of soldiers as a result of their indiscriminate and imprudent use of morphine was so widespread that the problem was publicly referred to as the "soldiers' disease" or "army disease".¹⁸

A second factor alleged to have contributed to a developing drug addiction at that time was the importation of Chinese. Following the Civil War Chinese workers were imported to assist as cheap labor in the building of our nation's railroads.¹⁹ These Chinese are purported to have brought with them and introduced into our culture the practice of opium smoking. No doubt in partial response to this the City of San Francisco in 1882 passed an ordinance forbidding opium smoking under the threat of heavy penalty.²⁰ The State of New York is alleged to have followed suit directing its attention to opium smoking in New York City's Chinatown.²¹

16. This is not to say that laws are to be enacted in direct support of moral principles, nor primarily for moral purposes. It is to say, however, that they ought not to be immoral either facially or as applied.

17. There is little doubt in this author's mind that both nicotine and alcohol are potentially dangerous drugs. Nonetheless I do not intend to herein deal with them except insofar as laws controlling them and societal attitudes regarding those laws shed light on laws controlling the other so-called dangerous drugs, i.e., heroin, LSD, cocaine, marijuana, MDA, DMT, barbiturates, amphetamines, etc.

18. O. Ray, *Drugs, Society and Human Behavior* 18 (1972) [hereinafter cited as Ray].

19. *Id.* at 18.

20. H. H. Kane, *Opium Smoking in America and China* (1882.) Correspondence between the Author and the official custodian of records for the City and County of San Francisco has confirmed that such an ordinance was passed on June 11, 1903. There are no official records available for 1882, due no doubt to the great earthquake and fire. See San Francisco, Calif., Ordinance No. 798, June 11, 1903.

21. Ray, *supra* note 18, at 18.

By 1898, an advance in German chemistry resulted in the discovery of diacetyl morphine, commonly known as heroin.²² For a limited period of time heroin was thought to be a panacea for morphine addiction and it was medically prescribed as such.²³ The cure proved to be more painful than the illness.

Finally, the widespread legal distribution of patent medicines, dispensed by traveling peddlers, was an additional major factor which allegedly contributed to an increasing opium dependency problem in the United States.²⁴ Whether this is true or not remains a subject of debate but it is clear that the passage in 1906 of the Pure Food and Drug Act, which prohibited the interstate commerce of adulterated or misbranded drugs, was in response to a growing public concern over the use of patent medicines.²⁵

In 1909 the importation of opium, except for medicinal purposes, was declared illegal.²⁶ It is at this point in time that the fragmented and piecemeal approach on the federal level to drug control legislation finds its origin. Although designed to prevent opium smoking and its associated evils from taking root the act did not render it illegal to use or manufacture opium for non-medical use, but merely banned its importation. In fact, it was not until 1942, with the passage of the Opium Poppy Control Act, that there was a sound legal basis for controlling the cultivation of the Opium Poppy in the United States.²⁷

It is the firm opinion of one well-cited author in the field of drug addiction and law that public opinion and medical opinion had little to do with the formulation of our federal policy regarding the handling of drug problems. Rather, he argues:

"It is a program which, to all intents and purposes, was established by the decisions of administrative officials of the Treasury Department of the United States. After the crucial decisions had been made, public and medical support was sought and in large measure obtained for what was already an accomplished fact."²⁸

One has great difficulty in quarreling with Lindesmith's position regarding the role of administrative officials, particularly within the Treasury Department, with respect to shaping and administering drug laws. The earliest and most comprehensive federal law dealing with the subject of narcotic drugs, the Harrison Narcotic Act of 1914²⁹ was entitled as follows:

"An Act to provide for the registration of, with collectors of Internal Revenue, and to impose a special tax upon all persons who produce, import, manufacture, compound, deal in, dispense, sell, distribute or give away opium or coca leaves, their salts, derivatives or preparations and for other purposes."

Although the declared object of this law was to provide revenue its ostensible purpose appeared to be one of rendering the entire process of drug distribution within the United States a matter of record. Under the terms and provisions of the Harrison Act, all dealers and dispensers of narcotics (opium, cocaine and their derivatives) were required to register annually with the Internal Revenue. A nominal excise tax was collected by the Treasury Department on the transfer of any of the described drugs.³⁰ The Act as originally passed was not punitive in approach but was intended through its recordation provisions to limit addicts to lawful channels of distribution for their drugs. Nonetheless an illicit drug trade developed follow-

23. See Terry and Pellens, *Id.* at 76-82.

24. Birney's Catarrh Cure contained 4% Cocaine while Laudanum contained 1 grain of opium for every 25 drops of alcohol. Ray, *supra* note 18, at 18. This provides a striking parallel to the much more dated "Golden's Liquid Beef Tonic" which in the 19th century was an oft recommended tonic treatment for alcoholism, despite the fact that it contained 53 proof ethyl alcohol.

25. The Food and Drugs Act of June 30, 1906, ch. 3915, 34 Stat. 768. It should be noted that the original Act was concerned with misbranding and required that the drug package state how much and what proportion of the stated drug, e.g., alcohol, was therein contained. It was not primarily concerned with the safety (toxicity) nor the effectiveness of the drug. These two aspects were formulated into law by amendments occurring 32 and 56 years later, respectively. See generally 21 U.S.C. §301-392.

26. Opium Import Control Act of 1909, ch. 100, 35 Stat. 614.

27. Opium Poppy Control Act of 1942, ch. 720, 56 Stat. 1045; since 1909 Congress has enacted more than 50 pieces of legislation relating to control of narcotics. See generally H.R. Rep. No. 91-1444, Sept. 10, 1970, 91st Cong. 2d Sess. (1970).

28. A. Lindesmith, *The Addict and The Law* 1 (1965).

29. Narcotic Drug Act of Dec. 17, 1914, ch. 1, 38 Stat. 785.

30. No doubt this tax was designed to make clear the fact that this law was a taxing measure. Serious doubt existed in 1914 concerning the constitutional power of the federal government to legislate in the area of drug control. Clearly under the 10th Amendment states possessed such a police power. *Whipple v. Martinson*, 256 U.S. 41 (1921). In order to avoid this question of constitutionality the law was premised on the power of the Congress "to lay and collect taxes," contained in Article 1, Section 8 of the U.S. Constitution. The sale provisions of the Harrison Act were constitutionally upheld in *United States v. Doremus*, 249 U.S. 86 (1919), because they had some relation to the raising of revenue; see also *Jin Fuey Moy v. United States*, 254 U.S. 189 (1920).

g passage of the Harrison Narcotic Act and is said to have resulted in a charge to the user of a narcotic drug fifty times in excess of the legal retail drug price.³¹

Unfortunately and regrettably, the passage of the Harrison Narcotic Act left the status of the addict in limbo; he was not specifically mentioned or dealt with. It did not take the addict long, however, to realize that his source of drugs was the black market. He was helped in this decision by the United States Supreme Court which by a series of decisions created an intolerable situation for addicts as well as for physicians treating addicts.

Shortly after passage of the Harrison Narcotic Act the U.S. Supreme Court held that an addict's possession of morphine sulphate, prescribed for him by a physician, did not constitute a conspiracy in violation of that law.³² However, after having encouraged the addict to turn to a physician for his drugs the Supreme Court then ruled³³ that a prescription of drugs for an addict "[N]ot in the course of professional treatment in the attempted cure of the habit, but being issued for the purpose of providing the user with morphine sufficient to keep him comfortable by maintaining his customary use" was not a prescription within the meaning of the law. In fact "[T]o call such an order for the use of morphine a physician's prescription would be so plain a perversion of meaning that no discussion of the subject is required."³⁴

Three years later in the case of *United States v. Behrman*,³⁵ the Supreme Court, over the dissents of Justices Holmes, Brandeis, and McReynolds, held in effect that a physician's good faith intention in prescribing drugs to an addict was immaterial in deciding whether or not a particular dosage was a permitted "prescription" under the terms of the Harrison Narcotic Act.

These decisions by the Supreme Court did more than deprive an addict of a legal source of drugs to ameliorate his pitiful condition—they also put an end to a unique experiment with ambulatory

drug clinics. In 1919 New York City opened the first such clinic and a favorable public attitude toward assisting the addict resulted in the opening of 43 more throughout the United States.³⁶ By 1923, due in no small part to the efforts of the federal narcotics authorities, all of these clinics were closed—done so without one critical analysis of the treatment methodology.³⁷

Coincidental with the Behrman decision in 1922, public opinion began to mold and to reflect administrative and judicial attitudes toward the addict. Thus it was that the Jones-Miller Act of 1922,³⁸ which more than doubled the maximum penalties for dealing in imported narcotics was warmly received and, in fact, demanded by the public. "The addict was no longer a victim, but a threat, a transformation that took but four years to accomplish."³⁹

Ironical as it must have been, the Supreme Court, three years later, in *Linder v. United States*⁴⁰ took a critical turn in its approach to medical issues arising under the Harrison Act. For the first time the Court seriously questioned the wisdom and the constitutionality of its prior practice of applying the provisions of the Harrison Narcotic Act in rigid fashion to situations involving the prescription of drugs by physicians to addicts for the purpose of relieving conditions incident to addiction. In terms of impact, the Linder opinion involved much more than a seeming retreat from the Court's earlier decisions in *Webb* and *Behrman*. Indeed, the Court in *Linder* made explicit the fact that, "Obviously, direct control of medical practice in the states is beyond the power of the Federal Government."⁴¹ Significantly, based on this premise, the Court reasoned that because "[A]ddicts are diseased and proper subjects for such [medical] treatment," the Court could not possibly conclude that a physician acted improperly or unwisely or for other than medical purposes solely because he has dispensed to one of them, in the ordinary course and in good faith, four small tablets of morphine or cocaine for relief of condi-

tions incident to addiction.⁴²

Linder remains good law⁴³ though it has been argued that in years subsequent to the decision few physicians relied on it—largely owing to a fear of playing “Russian Roulette” with the law. Their fear was not unwarranted for as late as 1936 the U.S. Treasury Department continued to maintain regulations purporting to instruct physicians as to when they may and may not prescribe drugs for addicts.⁴⁴ An additional factor which may have served to hamper the medical profession with respect to prescribing drugs for addicts is the fact that even after Linder the Courts retain the right to pass upon the question of a physician’s “good faith”, and this provides the medical profession with something less than complete certainty in the matter.

Until 1970 the Harrison Narcotic Act of 1914, as amended, remained the basic narcotic control measure. It has been amended numerous times but two are worthy of mention: The 1951 Boggs Amendments⁴⁵ and the Narcotic Control Act of 1956.⁴⁶ These statutes are further examples of a harsh and extreme legal approach to the problem of drug use and addiction. In reaction to what was viewed as an increasing addiction problem during the period 1948-51, these laws collectively imposed harsher penalties, virtually eliminated the possibility of unlawful probation for convicted drug offenders and (except for first offenses of possession) provided for mandatory minimum sentences upon conviction. As a practical result of the passage of these amendments judicial power and discretion were transferred to the police and prosecutors. *All* convicted sellers or distributors of narcotics were to be jailed or imprisoned. The possibility of overkill was at its height!

It was not until 1965 that the federal government regulated for the first time by statute, the possession or sale of “soft” drugs, e.g. barbiturates, amphetamines and Lysergic Acid Diethylamide (LSD). With the passage of the Drug Abuse Control Amendments of 1965,⁴⁷ barbitur-

ates, amphetamines and hallucinogens were brought under federal statutory control.

Whatever the reason for prior non-action with respect to these drugs may have been it is clear that there was a visible attitudinal change on the part of the U.S. Congress in 1965. This legislative enactment was devoid of the punitive tone and seemingly harsh approach to the drug problem which earlier federal narcotics and marihuana laws had possessed. Penalties for violation of the possession and sale provisions of this Act were in sharp contrast to those provided for violation of the oft-amended Harrison Act. For example, in 1965 the maximum penalty upon conviction of unlawful possession of amphetamine was one year imprisonment or a fine of \$1000 or both; probation and parole were also made available to the defendant.

There are several explanations for this differing legislative approach toward the sale or possession of these drugs. The distribution of amphetamines to soldiers during World War II and during the Korean conflict for the ostensible purpose of reducing fatigue and increasing alertness provides an analogue to the distribution and availability of morphine during the Civil War. The widespread use of amphetamines during the 1950’s by truck drivers, housewives, students, and others would seem to have pointed the way toward concern. Yet as late as 1963 the American Medical Association’s Council on Drugs stated: “At this time, compulsive abuse of the amphetamines (is) a small problem . . .”⁴⁸ Perhaps this is but another way of saying that rulemakers did not officially disapprove of amphetamine use until it became a cultural problem, i.e., the use of “speed” and other such drugs became associated with the rebellious youth movement and counterculture. Certainly, as one well versed author in the drug field has pointed out, laws against drug use provide a convenient device for attacking youth and stifling dissent and non-conformity.⁴⁹

The foregoing constitutes a nutshell overview

f the legislative history, on the federal level, of our narcotics and soft drug control laws. These laws were criminal in nature, all were thought to be responsive to the immediate problem and all were vigorously applied and enforced. Nonetheless, it should be noted that, during the period of their passage and following, drug use and dependency steadily and rapidly increased.

If the purpose of a criminal law is to deter the proscribed conduct then apparently narcotics and "soft" drug laws have failed in achieving that objective. If, on the other hand, the real purpose of a criminal law is to mete out punishment for having engaged in proscribed conduct then the narcotics laws have certainly been successful and effective. Jurisprudentially, however, and in either event, one of the primary purposes of a criminal law ought to be to protect society from forms of behavior which have been determined to be harmful and inimicable to the interests of society and its individual members. Has such harm been sufficiently demonstrated at the threshold point, i.e., before the Congress and the legislatures, or, at a later judicial point, with respect to: a) addiction; or b) simple and voluntary use for personal pleasure of any of the narcotic drugs or the dependency producing substances discussed thus far?

This question is not easy to answer, particularly because of the difficulties one encounters in attempting to sort and evaluate past actions and events. It is clear, however, that the legislative process through which our drug control legislation has developed was something less than desirable with respect to basic analysis of these laws prior to passage. A sound analysis, it would seem, would have required that less reliance be placed on the testimony and statements of those about to be charged with enforcing a given law and more inquiry be made into the question of whether there should be such a law in the first place.

On the other hand, it is extremely difficult to conclude that the legislative judgment with respect to drug control and the need for the same was altogether faulty. We know, for example, that heroin has ruined many a life and a family during this 20th century. We see the ravages of crime being attributed on a daily basis to the need of drug addicts to obtain money in order to purchase dependency producing drugs. There are many ad-

dicts in our society and it is fair to infer that there would be many more were it not for criminal laws.

Yet in the area of drug control, even these facts beg the question as to whether there should be criminal restraints in the first instance. Once the judicial imposition of criminal status has taken place, the unwilling recipient discovers that such a status carries with it or attracts to it a host of social problems and disabilities. Faced with this, the future conduct of such an individual is often predictable; in this sense crime will beget crime. The responsibility for setting in motion such a chain of events is thus a serious one and should be discharged accordingly. Unfortunately, there are crimes which have been rashly created by legislative bodies and in the end our entire society has suffered for it. Indeed, there are few areas of the law which have as urgent a need for a total re-examination and inquiry into the basic legislative wisdom in creating criminal restraints as the "other one-half" of our drug control, marihuana laws.

"A rose by any other name . . ."

The recurring theme that legislatures have heard little if any medical, sociological or scientific testimony before enacting drug control legislation⁵⁰ certainly is valid with respect to marihuana legislation, both state and federal. Cannabis Sativa, also known variously as marihuana, Indian Hemp, kif, ganga, maconha, dagga, bhang, charaas and hashish, grows in most of the countries of the world, including all those in the Western hemisphere, Africa, the entire continent of Asia, Australia and the Indonesian archipelago. A few scattered varieties may be found in Europe. Although there are botanical affinities between the various subspecies of cannabis sativa, the amount of psychoactive components in the plant varies widely.⁵¹

Marihuana has long been used for medical and religious purposes. Indeed, it is claimed to have played a medical role in every country in which it has grown.⁵² Cannabis is presently used in Arabic and Indian medicine, and in the United Kingdom it may be prescribed by doctors in the form of an extract or tincture of cannabis.⁵³ Medical use of cannabis is mentioned as early as 2737 BC when it was recommended in China by Shen

Nung, physician, for female weaknesses, beriberi, constipation, absent-mindedness and surgical anesthesia. It was also used medically in India before 1000 B.C.⁵⁴

It is thought that cannabis (in the form of the hemp plant) was introduced into the United States by the early English colonists.⁵⁵ Cultivation of the cannabis plant for its fibrous content is said to have been simultaneous with the founding of the early American colonies.⁵⁶ Hemp fiber was the source not only of rope which was to find its way into the riggings of many ocean sailing ships but also of the rough fabric which covered westward-bound American pioneer wagons. Despite the fact that hemp farming was an accepted, respectable occupation, the second half of the nineteenth century witnessed a decline in the use of hemp rope and canvas. Paper industries and birdseed manufacturers found uses for hemp which shortly took up the slack, however.⁵⁷ The 19th century British botanist Gilbert Burnett is said to have noted that the seed of the hemp is very nutritious and "[c]hanges the color of the plumage of bullfinches and goldfinches."⁵⁸

From colonial times until at least the second decade of the present century, cannabis was used medicinally in the United States in the treatment of a variety of illnesses.⁵⁹ Between 1839 and 1900 more than 100 articles appeared in scientific journals describing the medical properties of this plant.⁶⁰

The introduction of injectable opiates in the latter half of the nineteenth century and of specific synthetic analgesics and hypnotics in the first decades of the twentieth century may have had some effect on the decline in the use of cannabis as a medicine.⁶¹ Nonetheless at the time of passage of the Marihuana Tax Act in 1937⁶² twenty-eight legal cannabis preparations remained to be withdrawn from the market.⁶³

During the beginning of the twentieth century public interest and concern about the use of mari-

huana as an intoxicant was limited. The reasons for this are probably twofold. Firstly, it is generally assumed that the smoking of marihuana was confined to Mexican workers residing in the southwestern portion of the United States. As long as the problem was confined to "that group of people" there was little need to be aroused from a legal and societal standpoint. Secondly it is important to recognize that in 1900 only a handful of states regulated traffic in narcotic drugs—opium, morphine and heroin—even though proportionately more persons were believed addicted to those drugs at that time than at any other time since.⁶⁴ Contributing to this state of affairs is the demonstrable fact of a lack of definitive public policy at the federal level on the subject of controlling addiction. Thus in terms of state and federal legislative priorities the problem of the use of addicting drugs by the general public in the early years of the twentieth century was certainly foremost in the eyes of legislators; concern about marihuana was to wait its turn.

The passage of the Harrison Narcotic Act⁶⁵ in 1914 not only established a new federal policy with respect to narcotics but also saw the implantation legislatively of fallacious seeds of reasoning which were to come to fruition in the 30's. Specifically it should be noted that during the period of time prior to passage of the Harrison Narcotic Act the Temperance Movement was actively and publicly espousing its principles. Despite the fact that this movement had for a long time been concerned only with the use of alcohol and nicotine, many of its premises were applicable "in spades" to the use of narcotic drugs. Use of narcotic drugs came to be seen as an immoral act deserving of eradication. Use of narcotics, it was thought, automatically escalated to dependence and excess, which in turn led to pauperism, crime and insanity.⁶⁶ Sociologically, narcotics use was seen to be prevalent among slothful and immoral populations such as gamblers, prostitutes and oth-

er undesirables. These attitudes, expressed so strongly prior to the passage of state and federal narcotics legislation, played no small role in the later passage of marihuana legislation.

Certainly both the extent and amount of use of marihuana as an intoxicant played a role in determining the timing of anti-marihuana legislation, both state and federal. New Orleans was one of the first major cities in the United States to encounter "the problem". Sometime between 1910 and 1920 jazz musicians, particularly drummers, are alleged to have begun actively using the drug, and in joyous displays of friendship, to have shared it with their friends. From this port city, dried plant leaves were shipped up the Mississippi to various river ports and from there cross-country to large cities.⁶⁷ Although by 1930 marihuana smoking was popular with blacks and other minority groups it did not enjoy widespread use and acceptance by the dominant white middle class culture groups. This combination of use by minority groups only and an apparent nonconcern on the part of the general public resulted in the lack of a definitive public policy on the matter.

Notwithstanding this lack of public concern about marihuana and its use, by 1931 twenty-one states had managed to restrict the sale of marihuana as part of their general narcotics statutes, one state had prohibited its use for any purpose and four states had outlawed its cultivation.⁶⁸ Standing alone this regulation is somewhat misleading. In fact, it is strongly contended that in those states which had passed such laws there was little, if any, evidence of public concern which could be cited in support of them.⁶⁹ The explanation for this apparent anomaly is furnished by two authors in the field who assert, with some merit, that state anti-marihuana legislation in the Western half of the United States was motivated primarily by ethnic considerations⁷⁰ and in the Eastern half of the United States by fears of substitution.⁷¹ Indeed they con-

cluded from their research that prior to passage of anti-marihuana legislation no state had undertaken "[a]ny empirical or scientific study of the effects of the drug. Instead they relied on lurid and often unfounded accounts of marihuana's dangers as presented in what little newspaper coverage the drug received."⁷² This conclusion is further supported by the National Commission on Marijuana and Drug Abuse which made the following statement:

"Not once during this entire period [prior to 1937] was any comprehensive study undertaken in this country of marijuana or its effects. The drug was assumed to be a 'narcotic', to render the user psychologically dependent, to provoke violent crime, and to cause insanity. Although media attention was attracted to marijuana use around 1935, public awareness was low and public debate non-existent."⁷³

In light of the foregoing one might ask how it was that the Conference of Commissioners on Uniform State Laws could in 1932 promulgate a model act under the terms of which marihuana was optionally classified as a narcotic and its sale or possession prohibited and punished as severely as that of other narcotics, and further, that the federal government could, in 1937, pass with little debate the Marihuana Tax Act which, as amended, provided punishments equivalent to those provided under the Harrison Narcotic Act for the unlawful sale or possession of opium, cocaine and their derivatives. It serves one well at this juncture to consider seriously the charge that a small group of individuals through its zealous and vigorous efforts was largely responsible for these repressive marihuana laws. That small group is alleged to have been Harry Anslinger, Commissioner of the Federal Bureau of Narcotics, and his fellow employee-agents.

In 1930 enforcement of the narcotics laws was vested in the Federal Bureau of Narcotics, headed by Commissioner Anslinger.⁷⁴ Many of these narcotics agents were former prohibition agents who had little knowledge about narcotics,

70. Specifically, the states of Utah, New Mexico, Texas, Montana and Colorado are alleged to have engaged themselves in "class legislation" directed against Mexicans. Bonnie and Whitebread, *supra* note 68, at 1014.

71. It is theorized that marijuana use had to be prohibited to prevent addicts from switching to it as a substitute for the drugs which had become more difficult to obtain after the passage of the Harrison and Volstead Acts. Bonnie and Whitebread, *supra* note 68, at 1019.

72. Bonnie and Whitebread, *supra* note 68, at 1021-22.

73. Marijuana Commission Report, *supra* note 64, at 16.

74. Act of June 14, 1930, ch. 488, 46 Stat. 585. It is claimed that this agency was the single primary factor influencing the course of drug regulation in the United States from 1930 to 1970. See generally King, *The Narcotics Bureau and The Harrison Act*, 62 Yale L.J. 736 (1953).

and less about marihuana. It is a fact of history that Harry Anslinger waged a virtual one-man war for over 32 years, from his powerful position as Commissioner, against the sale or use of marihuana. The tone of his attack is best exemplified by the following statement made by him just prior to passage of the Marihuana Tax Act in 1937:

"How many murders, suicides, robberies, criminal assaults, hold-ups, burglaries, and deeds of maniacal insanity it [marijuana] causes each year, especially among the young, can only be conjectural.⁷⁵"

The Uniform Narcotic Drug Act was a relatively non-controversial act at the time of its adoption in 1932 by the Commissioners on Uniform State Laws. It was drafted in conjunction with the advice and input of the American Medical Association⁷⁶ and after 1930, Commissioner Anslinger. By 1937, all of the states had some form of marihuana legislation. Thirty-five states had adopted this uniform act⁷⁷ and nearly all of those states had included the optional marihuana provision despite the lack of any scientific undertaking by the Commissioners on this subject. Although it is claimed that the Federal Bureau of Narcotics lobbied in each state legislature to insure the passage of marihuana legislation on the local level, it is cautioned that due to the firming public attitude toward narcotics in general that such legislation would probably have been adopted despite the Bureau's efforts.⁷⁸

The Federal Bureau of Narcotics did not confine its efforts to assisting state legislatures in the passage of anti-marihuana laws. Indeed its involvement at the federal level both prior and subsequent to the passage of the Marihuana Tax Act is quite remarkable.⁷⁹ This involvement was considered by the Bureau to be necessary because

of the serious nature of the problem. The primary task of the Bureau appeared to be one of educating the public and the legislators concerning the dangers of marihuana. Fortunately, history and scientific research have disproven and dispelled as myths many of the facts and beliefs enunciated and pronounced under the guise of education by the Bureau in the 30's. Nonetheless the amount and type of information disseminated by the Bureau is in large part responsible for the defensive posture in which marihuana finds itself today.

The passage of the Marihuana Tax Act can be characterized as an unwarranted abdication and delegation of legislative responsibility by the Congress to the Federal Bureau of Narcotics and the Treasury Department. Legislative action was instituted on April 14, 1937 by the introduction of HR 6385 in the House of Representatives. Hearings on the bill before the House Ways and Means Committee began on April 27, 1937. These hearings lasted five days during which time 12 witnesses appeared. Three of these witnesses represented the birdseed industry and had appeared to express their concern that they be permitted to use hempseed as a form of birdseed.⁸⁰ Four of these witnesses represented the Treasury Department in one capacity or another and spent their time before the Committee explaining the tax features of the proposed law.⁸¹ The remaining witnesses provided little testimony on the medical, social or scientific aspects surrounding the use of cannabis. In fact the one witness who questioned this deficiency, Dr. William Woodward, representing the American Medical Association, was accused of obstructionism and bad faith.⁸² Woodward, to his credit, had the audacity to question the competency of the medical evidence regarding cannabis which had

75. Anslinger, Harry J. with Courtney Cooper, "Assassin of Youth", *The American Magazine*, at 18, Vol. 124, (July, 1937).

76. Dr. William C. Woodward, Executive Secretary of the Bureau of Legal Medicine and Legislation of the American Medical Association, who was later to become an outspoken critic of the Marihuana Tax Act, prepared and submitted the first tentative draft of the Uniform Narcotic Drug Act at the 1925 meeting of the Commissioners. See Bonnie and Whitebread, *supra* note 68, at 1030.

77. Minnesota adopted the Uniform Narcotic Drug Act in 1937, as Ch. 74, Minn. Stat. 618.01-05. Marijuana was defined as a narcotic and its unlawful sale or possession punishable as a felony by imprisonment from 5 to 20 years or a fine of not more than \$10,000 or both. This statute was repealed in 1971 by Minn. Laws Ch. 937, Minn. Stat. 152.01 et. seq.

78. Bonnie and Whitebread, *supra* note 68, at 1034.

79. During the period July 1937, to June, 1939, 17 articles were published condemning cannabis. Of these, ten articles acknowledged explicitly or implicitly the help given by the FBN in furnishing facts and figures. See H. Becker, *Outsiders: Studies in the Sociology of Deviance*, 14 (1953).

80. An agreement was reached whereby birdseed would be sterilized with heat before being placed on the market for sale. Hearings on H.R.6385 before the Committee on Ways and Means, 75th Cong. 1st Sess. 74 (1937) [hereinafter cited as Tax Act Hearing].

81. The Marihuana Tax Act was also passed under the guise of a revenue producing measure. See note 30, *supra*.

82. Tax Act Hearing, *supra* note 80, at 116.

been presented to the House Committee.⁸³

If the Committee hearings were deficient from a legislative standpoint, then certainly the action of the House of Representatives in passing the Committee bill was even more so. With little debate the Act passed without a roll call vote.⁸⁴

Proceedings in the Senate on this Tax Act were even less protracted. Hearing from a total of seven witnesses, five of whom represented the hemp seed industry, the Senate Committee deliberated less than two hours on the matter! On August 2, 1937 the Marihuana Tax Act was signed into law and it took legal effect on October 1, 1937. Thus this important piece of federal legislation finds its genesis in conduct and deliberations of the Congress which might easily be considered reprehensible from a legislative point of view and unworthy of public respect.

The Boggs Amendments and the Narcotic Control Act of 1956 not only dealt with the unlawful sale or possession of narcotic drugs; these Acts also served to increase the penalties provided for upon conviction of unlawful sale or possession of marihuana.

In 1951, for the first time on the federal level, marihuana was lumped together with the other prohibited narcotics and uniform penalties were provided for violators of the Narcotic Drugs Import and Export Act⁸⁵ or the Marihuana Tax Act.⁸⁶ The Narcotic Control Act of 1956 followed suit when it increased penalties for the unlawful sale or possession of narcotics. These legislative actions are generally believed to have been premised on an increasing public belief that the use of marihuana led to the use of more dangerous drugs, i.e., the stepping-stone theory. Unfortunately for many, this Draconian legal approach of actively prosecuting marihuana violations and seeking to impose severe sentences upon convicted marihuana offenders, particularly sellers, remained the law of the land until 1970.⁸⁷

If You Will Permit Me To Opine

Certain facts about the historical development of our drug legislation give this author cause for concern. Why was it, for example, that the remarkable report of the Indian Hemp Drug Commission of 1893-94 which "[D]espite its antiquity and relative obscurity . . . remains in all probability the most complete and well-balanced treatment of marijuana (and cannabis, or hemp, drugs generally) in existence"⁸⁸ has been all but ignored by virtually every legislative body and court which has dealt with the subject of marihuana. In contrast with the House and Senate antics of 1937 this Commission heard from 1,193 witnesses, 335 of whom were medical practitioners.⁸⁹ Perhaps the answer lies in the fact that the report and its six volumes of appendices totalling 3,000 pages, constitute much too much reading for any one legislator. Granting such reading difficulties, however, such an omission, although understandable, is not excusable, particularly when it is a criminal law which is undergoing legislative consideration.

The Indian Hemp Commission report does not stand alone. Also totally overlooked by legislators (or at least when it came to making their decision) was a study done from 1931 to 1933 by the United States Army regarding the use of marihuana by soldiers stationed in the Panama Canal Zone⁹⁰ and another done during the period 1939 to 1944 by a 15-man committee, which consisted of two Ph.D.'s and thirteen M.D.'s appointed by former New York City Mayor Fiorello La Guardia.⁹¹ Taken together these studies fairly conclude that the smoking of marihuana does not lead to aggressive or anti-social behavior nor does it cause sexual overstimulation or lead to the commission of serious crime—a refutation of the continuing myths perpetuated by the Federal Bureau of Narcotics and Commissioner Harry Anslinger in particular.

83. *Id.* at 92.

84. A statement detailing examples of lurid crimes which had been furnished to the Ways and Means Committee was read to the members of the House with little adverse comment. See generally Bonnie and Whitebread, *supra* note 68 at 1061 and 81 Cong. Rec. 5689-92 (1937).

85. Ch. 202, 42 Stat 596 (1922).

86. Ch. 553, 50 Stat. 551 (1937).

87. The impact of *Leary v. United States*, 395 U.S. 6 (1969), which held that to require buyers of marijuana to register, file a written order form and to pay a transfer tax was in violation of an individual's 5th Amendment protection against self-incrimination, was softened by subsequent cases. See *Minor v. United States*, 396 U.S. 87 (1969) (fifth amendment not applicable to provision requiring marijuana sellers to sell only to those who have furnished an order form) and *U.S. v. Young*, 422 F. 2d 302 (8th Cir. 1970), cert. denied, 398 U.S. 914 (1970) (conviction under Marihuana Tax Act for interstate transportation of marijuana does not violate the 5th Amendment).

88. J. Kaplan, *Marijuana, The New Prohibition*, 115 (1970).

89. See generally Kittrie, *Marijuana, The Right to Truth*, 23 So. Carol. L. Rev. 361-370 (1971).

90. This study concluded that marijuana was a relatively harmless drug and it did not cause maladjustment in the user. See *Marijuana Smoking in Panama*, 73 *The Military Surgeon* 269 (1933).

91. The committee's report "The Marijuana Problem in the City of New York" (Jaques Cattell Press, 1945), minimized the dangers of marijuana.

Perhaps framing my concern in a more direct fashion will be of some value: Why were these reports and others on the subject consistently ignored during the period of time that marihuana and its sale, use and possession were increasingly criminalized? The answer to this question might well create cause for concern about our legislative treatment of the other drugs as well.

It is this author's firming opinion that our professions, the medical and legal, might well consider the possibility that our professional input into this broad area of drug use, dependency and control may have something to do with "the problem" itself. Not only does our contribution and performance in this field appear in retrospect to have been decidedly biased but indeed our minimal input appears in the main to represent little more than an amplification of the majority values of the culture and society in which we find ourselves. In short, our failure to exercise an objective and professional approach to the drug problem—one which is not only bias-free but meaningful as well—must be seen as one important reason why we find ourselves as we do today with widespread youthful disrespect for our system of law, distrust of professional opinion and a highly questionable legal infrastructure for the control of drugs of abuse.

If examples in support of the foregoing assertions are needed they abound. The major organ of the American Medical Association for the presentation of scientific papers as well as its editorial policy is the *Journal of the American Medical Association (JAMA)*. That journal has consistently taken a biased position regarding marihuana not only in its policy statements but also in the papers it selects and rejects for publication.⁹²

As early as 1933 JAMA was sufficiently informed to state in response to a query from a medical practitioner: "[T]hat [marijuana] smokers nearly always become imbecile in time" and that "[I]t must be admitted that 'marijuana' . . . may cause dementia."⁹³

Following publication of the *La Guardia Com-*

mission Report the JAMA editorialized in 1945 as follows:

"The book states unqualifiedly to the public that the use of this narcotic does not lead to physical, mental or moral degeneration and that permanent deleterious effects from its continued use were not observed on 77 prisoners. This statement has already done great damage to the cause of law enforcement. Public officials will do well to disregard this unscientific, uncritical study and continue to regard marijuana as a menace whenever it is purveyed."⁹⁴

Individual efforts as well as official organizations support the proposition that the medical profession in general bears some responsibility for the amount of misinformation concerning drugs which has been disseminated and perpetuated from one generation to the next. For example in 1951 when the Boggs Act was being considered before Congressional Committees, individual medical practitioners supported, by their testimony, police assertions that there was a link between marihuana use and ultimate heroin addiction.⁹⁵

In 1971 the President-elect of the AMA was widely quoted to the effect that the Association had evidence that the use of marihuana not only caused birth defects but impotence as well. "Although he later admitted that he knew of no such evidence he said that he had allowed the misrepresentation to stand because he wished to discourage marihuana use."⁹⁶ When asked about the loss of credibility among the young caused by this type of authoritative misrepresentation the President-elect is alleged to have responded: "I'm tired of these phrases about credibility gap and such. We're talking about the morality of our country and the loss of respect of law and order and authority and decency."⁹⁷

Such public expressions of opinion, particularly on the subject of marihuana, may some day come to haunt the medical profession. Many medical students, for example, have a differing attitude concerning marihuana. In a reported survey of 1,057 medical students by the Association of American Medical Colleges it was

92. Grinspoon, *supra* note 55, at 329. This author, an M.D., recites as factual the rejection for publication of the well-publicized Crancer Study which dealt with the effects of marijuana on one's ability to adequately operate a motor vehicle (cannabis significantly less dangerous than alcohol in this respect) while at the same time accepting for publication three papers negative towards the use of marijuana.

revealed that 30% were currently using the drug.⁹⁸ Comments indicated those who had used the drug the most (over 100 times) were sure it was not harmful.

In particular, the students indicated they were not paying attention to publications which say the drug is dangerous, including those of committees of the American Medical Association or the National Research Council. In fact, the students were willing to indicate that they relied on the opinions of their friends in making a decision to use this drug.⁹⁹

The position of the organized legal profession concerning drugs and the need for drug control legislation has in the main been premised on the same misunderstandings and biased attitudes as have in the past permeated the medical profession. One can account for this by recognizing, that lawyers too, in the public expression of their opinions, have all too often only mirrored prevailing societal attitudes and prejudices, which in many instances are the antithesis of informed objective opinions. This has occurred despite the fact that lawyers are intimately involved in the prosecution and defense of drug law violations and ought to be in an excellent position to evaluate such laws in terms of their fairness, efficacy, deterrent effect and value in general. In partial defense of the legal profession, however, it must be said that lawyers, particularly lawyer-legislators, are prone to defer to and rely on the informed judgment of their professional medical brethren. It would set dangerous precedent were lawyers encouraged to exercise their independent judgment on matters which, at least after 1925, are considered legitimate, but not exclusive, matters of medical concern.

In further (but not hostile) indictment of my fellow brethren let me take pains to point out that a resolution introduced at the 1972 Annual Meeting of the American Bar Association, in which it was proposed that the ABA go on record in favor of the repeal of laws punishing the personal use of marihuana, caused extensive and heated debate.¹⁰⁰ The stated proposition that use of marihuana does not lead to the use of

narcotics was denounced by a lawyer from Texas as "just pure buncombe."¹⁰¹ All of which is to say that although legitimate and honest factual debate continues over the use of marihuana, and other drugs for that matter, the inflammatory and emotional rhetoric of the 30's remains with us today.

Further Food for Thought

One strongly suspects that organized medicine considers use of an illegal drug as "drug abuse" (the legal profession certainly does) thereby in a certain sense creating problems both for themselves and the legal profession. Certainly at a minimum such a definition constitutes a gratuitous extension of the jurisdiction of the medical profession into an area commonly denoted as legal in nature, i.e., the enactment of legislation defining criminal conduct—the converse of the uncomfortable position in which our United States Supreme Court found itself in the early 1920's when it was defining by decision what constituted legitimate medical practice.

If the medical and legal professions are to be of any assistance whatever to each other with respect to defining drug abuse and rendering meaningful recommendations for its legal control it would seem elementary that both first recognize the perimeters of their jurisdictions and thus their professional responsibilities, and guide their actions accordingly. In mitigation of these implied charges, it must be conceded that the subject of drug abuse is only one among a number of subjects which can be said to be of mutual concern to both professions and thus inviting of jurisdictional tangles.¹⁰² Such a concession, however, must not be allowed to obfuscate the real issue involved and it bears restating, to wit, whether each profession has exhibited and conducted itself with regard to a sensitive issue in a manner which is directly and primarily responsive to the legitimate concerns of that profession as opposed to the values and concerns held by the public in general.

More than ever before it is incumbent upon the numbers of our professions to assert them-

101. *Id.* at 1074.

102. The definition of insanity has long plagued legal and medical scholars alike. Mutual cooperation is made all the more necessitous owing to the seriousness of the topic. For an example of an urgent plea for mutual cooperation, See S. Glueck, *Law and Psychiatry: Cold War or Entente Cordiale?* (1965).

selves and take unpopular stands when the facts warrant them. The fact of controversy within our professions as well as the merits of the respective conflicting positions should be freely and publicly aired, for it is only when we have a well informed public that we are able to lend any weight to their nonprofessional opinion, regardless of the subject matter.

It would seem that a condition precedent to informing the public is informing ourselves and being honest and candid in doing so. To disclaim any bias or prejudice on our part, for example, with respect to the topics of heroin and marihuana use, is to deny the fact that each of us is to some extent the product of our environment and subject to existing societal attitudes and pressures. Once recognizing this, certain steps can be responsibly taken. At a minimum we can, if we wish, lend some credence to our professional opinions by taking the neces-

sary time to adequately educate ourselves on the broad subject of drugs and their use. Ideally one might become immersed in the subject and emerge as an informed leader in this developing field of medical practice. In any event, to be meaningful, the educational process and inquiry must of necessity be factual in nature and grounded in academia—not police publications. Education of students on the subject of drugs and the effects of their use must truly be pedagogical in nature. Only then will public expression of medical and legal opinion in this highly controversial area of drugs, drug abuse and drug control begin to earn a respect, which though publicly accorded in the past, was for the most part undeserved.

There are those who will say that this autopsy and the opinions herein rendered are neither complete nor scientifically sound. To them I commend the body for further examination.

The Clinical Allergist and Immunologist

The Department of Medicine of the University of Minnesota Medical School announces a continuing medical education program entitled "The Clinical Allergist and Immunologist" to be held April 5-7, 1973 in the Nolte Center for Continuing Education on the Minneapolis campus. The program is presented by the Office of Postgraduate Medical Education.

This course is designed as an up-to-date survey of clinical allergy and immunology. Emphasis will be placed on the practical features of doing a sound allergic and immunologic work-up as well as treating patients in a safe and medically acceptable fashion.

In addition to lectures, demonstrations and question periods, practical workshops will be conducted on presclected topics by the members of the faculty.

Fee: \$100.00.

Further information may be obtained from the Office of Postgraduate Medical Education, University of Minnesota, Room 205, Nolte Center for Continuing Education, Minneapolis, Minnesota 55455, or by calling (612) 373-5454.

Laboratory Letter

Toxicology vs. the Laboratory

Laboratories are increasingly involved in a second aspect of toxicology. The tests for patient overdosage have a long history, and now we're increasingly involved in iatrogenic overdosage, either for the patients who are unusually sensitive to a drug or for the diseases which require a near toxic therapeutic drug level.

Salicylate levels are among the easiest to do—any lab with a colorimeter can do a quantitative test. Levels of less than 20 mg% are in the therapeutic range, and death may be expected at levels of over 50 mg%. A more accurate prognosis can be made with the aid of a nomogram that considers the time since ingestion.* Phenistix will often give a pink reaction when dipped in the urine of patients who have salicylate intoxication.

Quinidine levels are available but require laboratory instruments that are not available in every hospital.

Digoxin and digitoxin levels are now commonly available but only the fortunately situated patient and physician can get a result in one day. Digitalis toxicity is probably the most common adverse or toxic drug reaction in the hospital. Studies have shown that from 20 to 35% of digitalized hospital patients are toxic. According to the British Medical Journal, it has been in use for 200 years and we still don't know how to use it.

Digitalis levels approach toxic levels very easily: 30% of the lethal dose is a therapeutic level, and 60% of the lethal dose is a toxic level. If there are further complications, such as renal failure, (even mild reduction in the glomerular filtration rate), electrolyte imbalance, pulmonary disease, age, thyroid abnormality, variable absorption metabolism or drug potency, difficulty in achieving a therapeutic level is not surprising. Perhaps the

FDA would not approve it, if it was a new drug.

Usual serum levels are 1 to 2 ng/ml and over 3 ng/ml is almost invariably toxic. Values may vary according to laboratory methodology, so, as usual, it's best to check with your lab, and in addition, there may be significant differences in patient responsiveness. The physicians must have the serum drawn eight hours after the last digitalis dose, although drawing from six to 24 hours after the last dose may still provide useful, although less precise, information.

Classical toxicology, patient overdosage, remains a problem, as much a problem to the laboratory as to the clinician. Journal articles continue to be titled 'A Quick Method for Detection of Poisoning,' but the methods take a day or so to perform. Paper chromatography, as used to screen drug addicts, is neither fast enough nor quantitative. Certainly the quickest method for estimating the type and amount of ingested material is an investigation at the scene of the poisoning.

Alcohol is the most common patient overdosage and the toxic levels are well known. Its commonness leads to occasional overdiagnosis and most pathologists have received 'under the influence' patients who have actually died from another drug, perhaps in conjunction with alcoholic intake. Again, a careful history may provide the best immediate answer, although blood levels are available in many labs.

Barbiturate poisoning is still common. These drugs, in common with many others, are best identified by gas chromatography but this procedure will be reserved for a few laboratories that can afford the equipment and, more important, the specialized around-the-clock staffing. A serum level will usually take at least four hours and may take forty hours. Nevertheless, the following table may be of interest.[†]

*Minnesota Med April, 1965.

†Parker et al. Clin. Tox 3, Mar. 1970.

TABLE
Concentration of Barbiturate in the Blood vs. Degree
of CNS Depression

Barbiturate	Class Speed of onset Duration of action	Blood barbiturate level, ppm ($\mu\text{g/ml}$) Degree of depression ^a				
		1	2	3	4	5
Pentobarbital	Fast Short	2	0.5 → 3	10 → 15	12 → 25	15 → 40
Secobarbital	Fast Short	2	0.5 → 5	10 → 15	15 → 25	15 → 40
Amobarbital	Intermediate Intermediate	3	2 → 10	30 → 40	30 → 60	40 → 80
Butobarbital	Intermediate Intermediate	5	3 → 25	40 → 60	50 → 80	60 → 100
Phenobarbital	Slow Long	10	5 → 40	50 → 80	70 → 120	100 → 200

^aDegree of depression in nontolerant persons. 1—Under the influence and appreciably impaired for purposes of driving a motor vehicle or performing tasks requiring alertness and unimpaired judgment and reaction time. 2—Sedated, therapeutic range, calm, relaxed and easily aroused. 3—Comatose, difficulty aroused, significant depression of respiration. 4—Compatible with death in aged or ill persons or in presence of obstructed airway, other toxic agents, or exposure to cold. 5—Usual lethal level, the upper end of this range includes those who received some supportive treatment.

Phenothiazines can be semi-quantitatively evaluated in any lab with a simple ferric chloride urine test. This may be of value as an easy ruleout test.

Carbon monoxide poisoning accounts for about half of the fatal poisonings. In the hospital, or in chronic cases, diagnosis may be obscure. Pink skin will not be seen, although in severe cases the blood may be (slightly) brighter red. If no suggestive history is available, the symptoms of a feeling of fullness in the head, followed by headache, nausea and vomiting, and finally drowsiness and coma, may unfortunately be nonspecific. Mild, chronic cases may have palpitation, tachycardia, fatigue, nausea and headache. In acute cases, oxygen will relieve tachypnea and eliminate half of the carbon monoxide in thirty minutes or less, before the lab results are available. Levels of 7% or less may be found in smokers (even more in traffic policemen, who may be symptomatic), levels of over 10% may cause symptoms and death is common if the hemoglobin saturation is over 50%.

Acute or chronic lead poisoning is said to occur more frequently than appreciated. A simple, fluo-

rescent urine test can detect many cases when there is no time for the quantitative tests. Glutethimide poisoning is increasingly popular, and remains difficult for the laboratory to very quickly confirm.

Organic phosphorus insecticide poisoning will probably increase due to the banning of DDT, which is nearly non-toxic to humans. The substitutes, such as parathion, are highly toxic and absorbed by all routes, even through the skin. Fortunately, specific therapy is available. Screening tests for the affected cholinesterases are available; normal levels will vary according to the procedure that is used. A quantitative test is also available, and both procedures are the same as used to detect succinylcholine sensitivity.

When history is insufficient there remains what the FBI calls 'the general unknown.' Until recently this was a very difficult identification task. It is now possible to analyze these specimens with gas-liquid chromatography and paper chromatography, but for most acute poisoning cases, limited immediate availability subtracts from the usefulness of chromatography and we're back to relatively blind treatment of symptoms.

Community Abortion Services

The Role of Organized Medicine

JANE E. HODGSON, M.D.*

SINCE THE RECENT Minnesota Supreme Court statement regarding the unconstitutionality of the Minnesota abortion law, there is no longer any legal impediment to the delivery of this medical service. Yet hospitals are cautiously eyeing one another, newspapers are speculating as to the policy each hospital will assume—and women are still forced to leave the state to terminate unwanted pregnancies.

As of this writing, three weeks since the momentous overturn of our nation's restrictive abortion laws by the U. S. Supreme Court, there has been no official reaction by organized medicine except one statement, which, unfortunately, seemed inconsistent and lacking in breadth and objectivity.

Dr. Charles A. Hoffman,³ president of the American Medical Association, recently deplored the Supreme Court ruling, and predicted a surge in the number of abortions that would be performed. "I am not a prude, but I am saddened and concerned about the seemingly lackadaisical attitude toward the taking of human life." But, in another statement concerning the shortage of medical facilities and doctors he added, "Improved medical health care is not a need of the people of this nation . . . it is a demand." It is difficult for him, as well as the rest of the medical establishment, to concede that pregnancy termination is part of health care. In women's struggle to gain control of their reproductive lives, the medical profession has been a most reluctant ally.

Similarly in the battle to legalize contraception, it was Margaret Sanger, the ministry, the legal profession and social workers who were the leaders. It was the Clergy Counseling Service who defied the legal restrictions on abortion, and relieved the patient pressure on physicians by referring their patients with unwanted pregnancies to Japan and Mexico, and after 1970, to New York state and California. But the doctors were scarcely aware of the details of the methods used. When so-called "legal" abortions were performed in

American hospitals, the old conventional methods were used—namely, a D&C under general anesthesia, accompanied by the hazards of a general anesthetic, increased bleeding, 2-3 days hospitalization and several hundred dollars of expense. No advances in technique had occurred since the old abortion laws had been written over one hundred years ago.

Consequently when New York state repealed its century-old abortion law in 1970, very few American physicians were familiar with the newer, safer techniques being used in Eastern Europe and Japan where abortion had been legalized for 30 years.

The majority of U. S. physicians had never performed even a "therapeutic" abortion. Gynecological specialists were unprepared to cope with the large number of women asking for quick, painless and low-cost abortions. An influx of patients into the medical system, combined with a shortage of participating physicians resulted in excessive fees. Established gynecologists and academicians maintained an aloof attitude because of the "shadowy" nature of the services to be provided.

The challenge to the New York medical profession was almost overwhelming, but their response to this medical crisis was indeed remarkable. The time has now come for each state to care for its own. Let us hope that Minnesota will not be found wanting.

In the years from July 1970 to July 1972, the physicians of New York state performed 402,059 therapeutic abortions and provided sufficient statistics to document the safety of the procedure and advantages of certain techniques.

Gordon Chase,⁴ the Administrator of New York City Health Service Administration, released the following information in November 1972:

In 1970-71 there were three first-trimester abortion deaths for a rate of 2.1 deaths/100,000 abortions; and in the second year (1971-72) this decreased to 0.5/100,000 abortions, indicating an

*Medical Director, Preterm, Washington, D.C.

extremely small risk attached to first-trimester abortions. Complication rates for first-trimester abortions dropped from 4.6/1000 abortions during the first year to 3.0/1000 abortions in the second year.

Mr. Chase further pointed out the definite improvement in the maternal mortality rate due to the decline in criminal abortions. The over-all maternal death rate in New York for the two-year period under the new law was 37.7 deaths/100,000 live births, a decline of 28% from the preceding two-year period when it was 53.2 deaths/100,000 live births. Infant mortality dropped to an all-time low in 1971 and out-of-wedlock births declined for the first time since 1954—a drop of 11.8%.

Legalizing abortion reduces illegal abortions, illegitimacy and abortion-related fatalities. In addition, we may conclude that abortion is "safe" when performed by vacuum aspiration during the first trimester. Procedures performed in the second trimester entail a risk three to five times as great.

In a recent decision this past June, the Federal Court of Appeals declared unconstitutional Maryland's therapeutic abortion law requiring that abortions be performed only in licensed, accredited hospitals.² This was a first and very important step in legitimizing the role of free-standing clinics in community abortion services. Following the testimony of Dr. Irving Cushner, Dr. Allen Barnes, Dr. Christopher Tietze, and others, Justice Young found as a fact that the requirement that abortions be performed only in licensed, accredited hospitals places a burden on women's rights to such an abortion, which burden would be lightened by permitting abortions to be performed in other facilities. With appropriate regulations, facilities other than hospitals can and do protect the health of the woman seeking an abortion as adequately as hospitals do.

In 1968 at the time that Maryland's Therapeutic Abortion Act had been passed there was little knowledge of the demands on hospital facilities under a liberalized law. The feasibility of legalized abortion was not yet established, nor were the types and seriousness of complications determined; hence the mandatory law regarding hospitalization. The real focus of attention then, only four years ago, was on the *reasons* for abortion, rather than *where* they should be performed. Now we have

experience to draw upon, which is the basis for the recent Maryland decision against mandatory hospitalization.

During the hearing outstanding testimony was offered by Dr. Christopher Tietze² who referred to the oft-quoted Joint Program for the Study of Abortion Report (JPSA).⁶ Dr. Tietze pointed out that, according to JPSA the complication rate in abortions performed by vacuum aspiration in the first trimester of pregnancy was lower for the non-hospital clinics than for hospitals, and was also lower for hospital out-patient cases than for hospital in-patients. He further pointed out that the complication rate for early abortions by suction has been declining steadily, and declined approximately 50% from the third quarter of 1970 to the second quarter of 1971. This decline he felt was attributable in part to the increased skill of the physicians which comes from substantial experience in performing abortions.

Advantages of a Free-Standing Clinic

It has become apparent that it is not necessary to keep patients overnight, inasmuch as complications, if they do occur, usually begin three to five days later. Mandatory hospitalization places great strain on the availability of hospital beds, costs are increased, and scheduling delays result. At the present time it would seem impossible for hospitals to compete with the low fees offered at the free standing clinic.

Another advantage offered by the free-standing clinic is the greater ease with which problems concerning personal objections of physicians and paramedical personnel may be handled. Such problems are constantly arising in hospitals at the present time. Obviously it is not desirable to use physicians or paramedical personnel who view the procedure with disapproval. Sympathy with the women who have an unwanted pregnancy is required. Furthermore there is no place for restrictive hospital committees, except possibly to analyze statistics and evaluate techniques and complications.

Requirements of spousal and parental consent are rapidly being declared unconstitutional by the courts. As was so aptly stated by 100 professor of obstetrics in a recent statement on abortion "Any girl who is physically mature enough to conceive, should, *ipso facto*, be granted the freedom to determine the fate of her pregnancy."⁵

There are unique medical problems surround

ing the abortion patient. These women must be handled individually according to their special needs, and rigid hospital routines are not easily individualized. In contrast to hospital patients, these women are physically well and do not require the care and regimentation necessary for the truly sick.

They may use fictitious names and addresses. They may have no funds or insurance should complications arise which require hospitalization. Thankfully the pall cast over the procedure from illegality will soon be a thing of the past. Follow-up care and treatment of complications should improve greatly under the new legal status.

PRETERM Experience

PRETERM was conceived in March 1971 as a non-profit, tax-exempt, corporation, which is a total family planning agency located in the District of Columbia. The importance of integrating counseling, contraception, sterilization and abortion into one family planning clinic was emphasized. The value of personal counseling on a one-to-one basis was to be tested. Abortion, sterilization, contraceptive advice and sexual counseling were to be offered as necessary medical services, deliverable in a safe, humane, and inexpensive manner.

A high quality of service was maintained by the restricted use of board-qualified personnel (certified obstetricians and gynecologists). The importance of a healthy clinic-hospital relationship was emphasized.

Strict limitation of patients to those women whose length of gestation is ten weeks or less from conception date (12 week, LMP) has been a very important factor in maintaining a low complication rate. Medical and surgical complications are carefully screened and the higher-risk patients referred to a hospital setting.

High standards of care are also maintained by the integration of an active teaching program. There is an on-going training program for physicians, nurses, and paramedical personnel. High quality care is also maintained by careful record-keeping with analysis and publication of computerized data.

Community Role

Another important role of the free-standing clinic in community abortion service is participa-

tion in sexual and contraceptive education in the school system and adult organizations. A speaker's bureau is maintained to respond to calls from the community. Radio and television appearances are frequently made by the staff.

Another community service is the provision of free pelvic examinations, pregnancy tests, and gonorrheal cultures on a walk-in basis.

Treatment for gonorrhea and follow-up therapy is provided free of charge.

By applying principles of sound business organization and management, the cost of medical services can be decreased by several factors:

1. Utilization of paramedical personnel instead of physicians where possible.
2. Physicians are salaried instead of being paid on a fee-for-service basis.
3. High patient volume (60 abortion procedures/day).
4. Maximum utilization of physical plant (six days each week).

The \$125.00 fee paid by the patient includes: laboratory charges, abortion procedure, follow-up examination if desired, contraception, personal counseling and the administration of Rh_n (D) — immune globulin (human)* where indicated.

Seventy-two appointments are made by telephone each day. There are a few "no-shows" each day, as well as referrals of patients to other agencies. The result is an average schedule of 60 vacuum aspirations/day, six days a week.

Everyone is on a first name basis and anonymity is guaranteed. The personnel are not required to wear uniforms, and patients do not undress. There are no routine medications. If the patient is not a candidate for an abortion procedure, every attempt is made to refer her to the proper agency.

During 23 months of operation over 24,000 abortions have been performed, with no mortalities, low complication rates, and intensive counseling for each patient. Ninety-four percent of these patients accepted some method of contraception at the time of the procedure.

In 1973 the free-standing clinic serves as the main source of delivery of this highly specialized service. At the present time, the free-standing clinic can terminate first trimester pregnancies far more economically and expeditiously and with a better safety record than the usual hospital. Treatment can be individualized and humanized more readily in the free-standing clinic than in the impersonal and highly regimented hospital

*RhoGam.

with its actually sick patients. Clinic personnel can be more carefully screened and become more highly specialized. The clinic environment furthermore lends itself more readily to abortion counseling and contraceptive education than does the hospital.

In the 24,000 abortion procedures performed at PRETERM, no complications have occurred because of, or were affected by, our ten-minute separation from a hospital. Undoubtedly, some real emergencies can and will occur, such as perforations, hemorrhage, and novocaine reactions. Therefore, the typical physician's office is not

adequate in regard to personnel, equipment, counseling, or general organization. Pregnancy termination is a highly specialized service, one that is not easily forced into our costly and complicated hospital systems—at least until hospitals can accommodate their prices and routines to meet the existing demands.

Perhaps the time will come when the free-standing abortion clinics will be administered and absorbed by hospitals. But in the meantime, let us overcome our lagging leadership and get on with the work at hand. As Dr. Allen Barnes once said, "The time to start was yesterday."¹

MONSIEUR FILERIN: Have you no shame, gentlemen, to show so little prudence for men of your age, and to quarrel like young fools? Don't you see how much harm such quarrels do us among the public? And isn't it enough that wise men see contrarieties and dissensions among our authorities and ancient masters, without also revealing to all people, by our arguments and quarrels, the quackery of our art? . . . These disputes do medicine no good. Since heaven has been gracious to us for so many centuries to make people infatuated with us, let's not disabuse them with our extravagant cabals; let's profit by their foolishness as charmingly as we can. We aren't the only ones, you know, who try to get an advantage through human weakness. That's what the greater part of the world studies . . . But the greatest weakness of men is their love of living; and we profit from it by our pompous nonsense, and we know how to get ahead through that veneration which the fear of dying makes them have for our profession.*

Glossary

Drug Related Terms

DUNCAN JONES,* AND MICHAEL RALKE*

Acapulco Gold—*high grade of marijuana, [somewhat gold in color], supposedly grown in the area of Acapulco, Mexico.*

acid—*LSD-25.*

acidhead—*LSD user.*

amped—*high on stimulants, usually amphetamine.*

angel dust—*powered PCP, (phencyclidine or "Seryl" an animal tranquilizer), taken alone, or smoked with marijuana or some other leafy material.*

bag—*about an ounce of marijuana or other drugs, usually in a plastic bag, sandwich size or the size used in coin shops.*

bandits—*chemicals produced in a non-pharmaceutical setting.*

barb—*any CNS depressant that is not a tranquilizer, opiate or synthetic opiate.*

black beauty—*Biphetamine.*

blow the vein—*the use of too much pressure when injecting into a weak or sclerosed vein.*

blue devils—*Amytal sodium.*

bombed—*usually drunk, could mean high on any drug, more often referring to a depressant high.*

bread—*money.*

bummer—*any negative experience, or a "bum trip."*

bum trip—*negative experience under the influence of a drug, usually hallucinogenic.*

burn—*to swindle someone into buying a misrepresented chemical.*

burned out—*someone who has suffered damage from drug use over a long period of time, or a state of being more serious than spaced out from drug use over a short period of time.*

busted or cracked—*to be arrested.*

buzz—*a slight pleasurable sensation, usually noticed in the region of the head, from the entrance of a drug into the body area to be affected.*

cactus—*referring to mescaline or the peyote cactus.*

cap—*usually a gelatine capsule containing a mood-altering substance.*

cartwheels—*usually amphetamine sulfate, in tablet form, with a crisscross scoring on one side.*

chick—*chauvinist or street term for a female; cocaine.*

chillum—*funnel shaped pipe used to smoke marijuana, marijuana and hashish, or hashish and tobacco.*

chipping—*using a chemical on an infrequent basis, usually referring to the more psychically and physically addictive drugs.*

Christmas Tree—*Dexamyl.*

cibas—*Doriden.*

coke—*Cocaine.*

cold turkey—*to withdraw from a physically addictive chemical, without the aid and comfort of other medications.*

coming down—*a state of being following the peak effect of a drug.*

con—*to swindle or manipulate.*

connect—*to purchase an illicit drug.*

connection—*the person with whom one connects.*

contact high—*to experience vicariously the high of a drug without having taken it.*

cop—*to connect for a chemical.*

*Co-directors of "Pharm House I" located in the West Bank Area of Minneapolis.

GLOSSARY

- cop to**—to admit to, or 'fess up'.
- co-pilots**—amphetamines, usually Benzedrine.
- count**—the quality and/or quantity of an illicit drug purchase.
- crank**—amphetamines.
- crash**—to go to sleep.
- crash pad**—a place to crash.
- crystal**—Methamphetamine hydrochloride.
- cut**—to alter a drug by adding other substances, usually dilutants such as quinine or milk sugar.
- dealer**—illicit drug supplier.
- deck**—a small packet of a drug such as heroin.
- DET**—diethyltryptamine
- dexies**—Dexedrine, Dexamyl.
- dime**—ten dollars.
- dirty**—impure drugs, or an unsanitary needle.
- DMT**—dimethyltryptamine.
- dollies**—methadone.
- DOM**—dimethoxy-4-methylamphetamine.
- dope**—any psychoactive substance.
- dope fiend**—someone who uses dope (see above) in a fairly regular manner.
- do up**—usually referring to injecting a drug into the vein.
- downer**—any CNS depressant.
- drop**—to take a drug orally.
- dropper**—homemade syringe device employing an eyedropper.
- dust**—Cocaine.
- dynamite**—anything of excellent quality, (people, dope or music etc.)
- electric kool-ade**—beverage containing Emma or Miss Emma, referring to morphine.
- far-out**—see dynamite.
- fit**—usually referring to a hypodermic syringe, preferably glass on glass.
- fix**—an injection, usually intravenous.
- flashback**—a recurrence of a small or large portion of an hallucinogenic experience usually brought on by stress or stimuli strongly identifiable with the experience; seems to be a function of the memory and, more often than not, stems from a bad trip or a trip interrupted by other drugs (e.g. someone treated with large doses of thiorazine for a bad trip.)
- flash**—orgasmic euphoria induced by the intravenous injection of a chemical.
- football**—oval shaped amphetamine tablets.
- freak**—to become acutely fearful; one who adopts a counter culture life style.
- freakout**—an acute fear reaction usually due to hallucinogens.
- front**—to distribute drugs, usually in large quantities, on credit.
- get off**—when the drug is taking effect
- grass**—marijuana.
- hash**—strongest part of the marijuana plant, the resin of the flower tops.
- head**—a person who uses dope, usually acid or grass.
- head shop**—a store which sells miscellaneous items for dopers, (posters, incense, pipes, marijuana papers, etc.)
- hearts**—amphetamines.
- high**—under the influence of a chemical.
- hit**—a single dose of a drug.
- hit up**—to inject intravenously.
- hog**—Benactyzine or PCP.

DRUG RELATED TERMS

- hold**—*to have in possession an unprescribed or illegal drug.*
- horse**—*heroin.*
- jacking off**—*masturbate, or repeatedly pumping one's blood into and out of the syringe to get the fullest effect from "the hit."*
- J**—*a marijuana cigarette.*
- joint**—*same as J, also a prison or jail.*
- jones**—*a physical dependence, usually on heroin.*
- junk**—*heroin.*
- junkie**—*usually referring to a heroin addict, any chemically dependent person.*
- key**—*a kilo of marijuana or hashish.*
- kick**—*a good feeling, or, more often, to stop using a drug in which one has been dependent.*
- lid**—*about an ounce of marijuana.*
- LSD**—*Lysergic acid diethylamide.*
- magic mushroom**—*or mushroom, referring to the psilocybin mushroom.*
- mainline**—*intravenous injection.*
- MDA**—*methylenedioxyamphetamine.*
- mescaline**—*an hallucinogenic derivative from the peyote cactus.*
- meth**—*methamphetamine hydrochloride.*
- meth freak**—*one who uses meth.*
- mike**—*microgram.*
- miss**—*the unsuccessful attempt to inject a chemical into a vein.*
- muscle pop**—*injecting the chemical into a muscle.*
- narc**—*a Federal Narcotics Agent.*
- needle flash**—*the sensation of the needle prick before the drug is injected.*
- needle freak**—*one who is imbued with the needle flash.*
- nickle bag**—*a five dollar quantity of a drug.*
- nodding**—*the act of slowly dropping ones head, repeatedly, after injecting a drug.*
- OD**—*an overdose.*
- outfit**—*the paraphernalia involved in intravenous injection, an eyedropper or syringe, a disposable needle, a gasket to seal the unit, and a spoon and a book of matches to 'cook up' or make injectable the chemical to be used by combining it with water and heating the mixtures and cotton to strain.*
- overamped**—*to be under the influence of a very high dose of an amphetamine.*
- Panama Red**—*reddish looking marijuana from Panama.*
- PCP**—*Serynl, phencyclidine, an animal tranquilizer.*
- peyote**—*a cactus from which mescaline is derived.*
- pig**—*policeman, or an unattractive person.*
- pill freak**—*one whose main form of drug use is taking tablets and capsules.*
- plant**—*an ignorant policeman's method of placing drugs in someone's possession.*
- point**—*needle for injections.*
- pop sub**—*cutaneous injections.*
- pot**—*marijuana.*
- psychedelic**—*substances that alter one's consciousness.*
- queen**—*a male assuming a female role in a homosexual relationship, or a male dressing in female clothing, usually called a "drag queen."*
- rainbows**—*Tuinal.*
- rap**—*conversation, usually not banal.*
- reds**—*Seconal, also called red devils.*
- reefer**—*a marijuana cigarette.*
- rip off**—*to steal.*

GLOSSARY

- roach**—*the end of a marijuana cigarette.*
roach clip—*mechanical device for holding the roach.*
rush—*see flash.*
scag—*heroin.*
score—*see cop.*
scrip—*a prescription, obtained illegally or legally.*
shoot—*to inject intravenously.*
shooting gallery—*a popular place to go to shoot drugs.*
smack—*heroin.*
snapper—*amyl nitrate.*
snort—*to inhale a drug through the nose.*
snow—*cocaine.*
sopors—*quaalude, a non-barbiturate hypnotic, becoming extremely popular in conjunction with beer and cheap wine, thereby producing the all-American high, falling-down stinko drunk*
speed—*any amphetamine.*
speed ball—*an injection of a stimulant and a depressant.*
speed freak—*one whose primary drug usage concerns itself with stimulants.*
spike—*hypodermic needle.*
spoon—*about a tenth of an ounce of a powdered drug, also used for preparing an injectable drug.*
stash—*one's personal supply of dope.*
stoned—*under the influence of a drug.*
STP—*a 48 to 72 hour hallucinogen, reported to stand for Serenity, Tranquility, and Peace.*
strung out—*actively dependent upon a chemical.*
THC—*tetrahydrocannabinol.*
tie—*anything tightly wrapped around the arm to make the veins stand out.*
toke—*oral inhalation of marijuana smoke.*
track—*the mark resulting from an intravenous injection.*
trip—*the experience while under the influence of a drug.*
turned on—*under the influence of a drug, sexually aroused, or just feeling good.*
vibes—*non-verbal communication, gut feeling for another individual.*
weed—*marijuana.*
whites—*dexedrine or benzedrine.*
wired—*under the influence of a stimulant.*
works—*see outfit.*
yellow jackets—*Nembutal.*
zip—*any amphetamine.*

A Review of "Endymion" by John Keats

It is a better and a wiser thing to be a starved apothecary than a starved poet; so back to the shop Mr. John, back to "plasters, pills, and ointment boxes," etc. But, for Heaven's sake, young Sangrado,* be a little more sparing of extenuatives and soporifics in your practice than you have been in your poetry.†

*Doctor Sangrado: a character in Le Sage's novel *Gil Blas*.

†John Gibson Lockhart or John Wilson, "Cockey School of Poetry No. IV," *Blackwood's Magazine*, August, 1818.

Regional Clearinghouses for Drug Abuse Information

With funds provided by a grant to the Minnesota State Planning Agency from the Governor's Commission on Crime Prevention and Control, and with matching funds from the Legislative Advisory Committee, the Drug Abuse Section of the State Planning Agency has set up a statewide network of Regional Clearinghouses for Drug Abuse Information. These Clearinghouses provide many services, and they are ideal as informative and referral centers for use by physicians throughout the State. Each Regional Director provides information about functioning organizations working with drug-related problems in his district. His office is a ready source of information and educational materials. In some regions, there are other services involved with drug crisis intervention that are open nights and weekends, when the Regional Clearinghouses are closed. The Drug Abuse Section of the State Planning Agency and the Minnesota Commission on Alcohol Problems have issued in 1972 a Directory of Alcohol and (other) Drug Programs in Minnesota, a copy of which will be sent to anyone requesting it. For a copy of that directory, write or telephone:

Bruce Bomier,
Coordinator of Drug Abuse Education
Drug Abuse Section, State Planning Agency
Suite 402, Metro Square Building
7th & Robert Streets
St. Paul, Minnesota 55101
(612) 296-3991

The Regional Clearinghouses for Drug Abuse Information serve areas shown in the Figure. They are:

In Memoriam

*They are not gone who pass,
Beyond the clasp of hand,
Out from the strong embrace.
Hugh Robert Orr, They Softly Walk.*

JOHN N. FERGUSON, M.D.

Dr. John N. Ferguson, 41, St. Paul internist, died January 22. He was born in Keokuk, Iowa, and graduated from the Washington University School of Medicine in St. Louis, Missouri.

He was a member of the Ramsey County Medical Society, the American Medical Association and the Minnesota State Medical Association.

His wife, Catherine, two sons, Gregory and David, and one daughter, Ann, survive him.

LEONARD ANTHONY VERANTH, M.D.

Dr. Leonard A. Veranth, 60, St. Cloud physician, died December 22. He was born in Ely and graduated from Marquette University Medical School, Milwaukee, Wisconsin.

He was a member of the Board of Directors of Minnesota Hotel and Motel Association, Stearns-Benton County Medical Society, the American Medical Association and the Minnesota State Medical Association.

Dr. Veranth is survived by his wife, Bernelda, son, Joseph, and daughter, Amy.

GEORGE CLARK ROTH, M.D.

Dr. George Clark Roth, 59, St. Paul internist, died January 15. Born in Boonville, Indiana, Dr. Roth attended Northwestern University Medical School in Chicago.

He was a member of the Ramsey County Medical Society, the American Medical Association and the Minnesota State Medical Association.

Dr. Clark is survived by his wife, Eleanore, two daughters, Patricia and Diane, and one son, George C., Jr., a physician.

BENJAMIN ANTHONY WEIS, M.D.

Dr. Benjamin A. Weis, former chief of staff of Miller

Hospital and past president of the Ramsey County Medical Society, died January 15. He was 68.

Born in Primghar, Iowa, he graduated from the University of Minnesota Medical School. Dr. Weis was a member of the Minnesota State Medical Association, the American College of Physicians, the American Medical Association, the Ramsey County Medical Society, the Twin Cities Diabetes Association and the St. Paul Chamber of Commerce.

Dr. Weis is survived by his wife, Lois, and three daughters, Mrs. John Rogers, Mrs. Thomas Skinner and Mrs. David Culligan.

WILLIAM H. THOMAS, M.D.

Dr. William H. Thomas, 51, Wayzata, physician, died January 9. He was born in Minneapolis and obtained his medical degree at the University of St. Louis. After practicing at Howard Lake for eight years, he joined a medical clinic in Lindstrom and was there for two years. In 1961 he started practicing in Wayzata.

Dr. Thomas is a member of the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association.

His wife, Judy and son, Ira, survive him.

OLAF A. OLSON, M.D.

Dr. Olaf A. Olson, 95, physician, died January 3. He practiced medicine in Minneapolis until he was 90. Born in Sweden, he came to this country with his family when he was just a small child. His medical education was obtained at the University of Minnesota.

He was a member of the Hennepin County Medical Society and the American Medical Association and a 50 Club and Life Member of the Minnesota State Medical Association.

Nieces and nephews survive him.

**She came from a nice quiet town
to find something stronger than marijuana.**

A lot of small towns think they
don't have any drug problem.
Because their drug problems
move away. And die someplace
else.

The cancer of drug addiction

has spread throughout the country
and we're not going to wipe it out
overnight.

But let's do something.
Let's get started. Troubled
teenagers are among the people in

this town who are crying out for
our help.

Poor people, sick people, old
people, disturbed people are
counting on us.

Give the United Way. Please.

If you don't do it, it won't get done.

Book Reviews

MODERN MANAGEMENT OF MENINGOMYELOCELE: Wilton H. Bunch, M.D., Ph.D.; Alexander S. Cass, M.D., B.S., F.R.C.S.; Alexander S. Bensman, M.D.; and Donlin M. Long, M.D., Ph.D., Warren H. Green, Inc., 320 pages, \$15.00.

Modern Management of Meningomyelocele stresses the interdisciplinary approach to management of the meningomyelocele child and anybody interested in habilitation of the handicapped child will find the book interesting and informative reading. The text has socioeconomic as well as medical significance since habilitation of most meningomyelocele children requires long periods of hospitalization and multiple surgical procedures. The authors believe, as does Durham Smith and others who have worked with these children, that it is less expensive to habilitate the handicapped child and allow him to become a functional member of society than it is to institutionalize him indefinitely. The merit or demerit of this approach is impossible to assess at present since, as the authors point out, none of the habilitated children have reached adulthood. Results to date, however, are encouraging and indicate, for example, that 60 percent of these children will be able to attend regular schools. In the past untreated meningomyelocele children who did not die in the first few months of life from meningitis (15 to 20 percent of these born with the defect) often lived for many years as hopeless cripples. The authors demonstrate convincingly that the goal of treatment is prevention of complications rather than correction of such defects once they have occurred; little can be done for the five-year old who presents with severe hydrocephalus, scoliosis, contractures, and uremia from urinary tract infection and vesicoureteral reflux.

While making a convincing case for habilitation of the meningomyelocele child from the child's and society's standpoint, the authors have not considered the effect of such a handicapped child on the family unit. Certainly, the lifestyle of a family who elects to raise their meningomyelocele child at home rather than to institutionalize him is changed considerably. It is particularly disheartening to see normal siblings neglected because the parent's time and resources are channeled, at times almost exclusively, toward the handicapped child.

The urological experience of Dr. Cass at the Gillette Hospital is of particular interest since he has had the opportunity to compare the results of conservative care (crede' voiding, catheter drainage, suprapubic tube, and vesicostomy) with a variety of different types of conduit drainage using large and small intestine. This study shows that early supravescical diversion can preserve renal function in patients who have normal urinary tracts and that renal function can be improved in some patients who have upper tract dilatation prior to surgery. The chapter on Orthopedics by Dr. Bunch, Neurosurgery by Dr. Long, and Habilitation by Dr. Bensman are equally informa-

tive and in comprehensive fashion cover the care of these children from birth to adolescence. This text should be required reading for anyone concerned with the care of the meningomyelocele child.

Daniel C. Merrill, M.D.
Minneapolis, Minnesota

SYNOPSIS OF GYNECOLOGY by Beacham and Beacham, 8th Edition; C. V. Mosby Co. \$10.90.

H. S. Crossen, in his preface to the first edition of this book (1932), pointed out that its primary value would be for medical students preparing for careers in unrelated specialties. The book has undergone numerous revisions and changes in authorship over the years, with the current edition being the first since 1967. The intended readership remains the same, however. Much attention, therefore, is concentrated on techniques of gynecologic examination and diagnosis.

There are some organizational difficulties in the chapter and subchapter arrangement, but the text itself is concise and highly readable. The illustrations are complementary and generally well done. The bibliographies, while not extensive, are pertinent.

Emphasis on such contemporary problems as contraception, and the inclusion of an interesting section on medicolegal aspects of gynecology, help make this a worthwhile and up-to-date mini-text.

Arthur H. Bearon, M.D.
Minneapolis, Minnesota

DIAGNOSIS AND TREATMENT OF HEMOPHILIA: A PRACTICAL GUIDE by Herbert S. Strauss, M.D. Albany Medical College, 86 pages, 3rd edition, \$3.50.

This short book reviews the entire field of coagulation. It offers much to the busy practitioner, the physician in training and to the interested nurse. The genetic basis, the carrier state, and newly described immunologic problems are well discussed. With only 11 of 85 references older than 1966 and many in the bibliography from 1972, the information is totally up-to-date. Further investigation by the reader is easily followed up by use of the excellent bibliography. Two points of controversy are found: factor VIII content in average pack of cryoprecipitate is fairly well accepted as being about 80-90 units rather than 110 units and normalization of the PTT after factor VIII replacement is not always true (and may in fact be misleading if unrecognized). The book can be read in 60-90 minutes and imparts much easily understood information. It belongs in hospital libraries and should be read by the doctor involved in either bleeding management problems or in diagnosis of such. No other publication covers so much in such a short space.

WAYZATA MEDICAL BUILDING OFFICE SUITES—Located in the fastest growing suburban area in the Twin Cities. We offer:

- Surrounding area of lakes, country clubs, woods, beautiful homes;
- Unsurpassed medical building facilities
- Fast growing area—high median family incomes
- Beautiful building—inside and out
- Inner courtyard with trees and landscaping
- Heated indoor parking
- Adjacent access to freeway system
- Low rental rates—favorable base terms
- Financial services

We have grown to fourteen specialties since our building was completed two years ago. We particularly are interested in Orthopedics, Psychiatry, Urology, Otolaryngology, Internal Medicine and Dentistry. Give us a call. We have a lot more to show you and to talk about. Reply to: Mr. Paske, Wayzata Medical Building, 250 North Central Avenue, Wayzata, Minn. 55391, (612) 473-0031.

ASSOCIATE FOR AAFP member in professional corporation or expense and call sharing association. New clinic building in construction to serve three rural communities. Immediate partnership in corporation, if desired. All corporate benefits immediately. Located in beautiful Hiawatha Valley of southeastern Minnesota, 35 miles from Mayo Clinic and 55 miles from Gunderson Clinic. Contact R. L. Sauer, M.D., Root River Valley Medical Clinic LTD., Box 496, Preston, Minnesota 55965.

ASSOCIATES WANTED: Family doctors to join a growing Family Practice Department in a large multiple specialty medical center, Minneapolis suburb. Excellent opportunity for teaching undergraduate and graduate students in Family Practice. Four man department with excellent growth potential. Reply to Dr. Harley J. Racer, Chairman Family Practice Department, St. Louis Park Medical Center, St. Louis Park, MN 55416. Telephone 612-927-3320.

FAMILY PRACTITIONER for rural area as member of 22 man multispecialty medical and surgical group. Opportunity for rural practice which incorporates advantages of membership in an urban medical group. Includes: *Educational programs:* Conferences, paid medical meetings, hospital rotations, peer review and support; *Quality Medical Care:* Ease of consultation, excellent lab and X-ray, regular call schedule and time off; *Economic Benefits:* Adequate salary, year end bonus, pension plan,

group disability, life insurance. Write 210 Ninth Street S.E., Rochester, Minnesota; or phone collect, J. J. Garber, M.D., 507-288-3443.

GENERAL PRACTITIONER needed as associate in county seat community of 2,000. Modern 35 bed hospital 4 blocks from fully equipped clinic. An excellent opportunity to live the good life in rural Minnesota. Write: Minnesota Medicine-477, 375 Jackson St., St. Paul 55101.

WANTED—Family physician to join two family physicians, a Board certified Internist, an Obstetrician—Gynecologist and Surgeon in well established clinic. Early partnership. Excellent hospital facilities, churches, schools etc. Call 612-425-2117 collect or write Osseo Clinic, Osseo, Minnesota 55369.

TWELVE MAN multispecialty clinic needs general practitioners ophthalmologists, otolaryngologists and internists. The present group includes surgeons, internist, urologist, gynecologist and generalists with family practice background. Northeastern Minnesota location with complete hospital facilities, excellent recreational country both winter and summer. Complete school system through junior college. Solid economic conditions. No big city problems. Profit sharing plan and pension plan. Beginning salary \$30,000 a year. Ownership participation after two years. Write MINNESOTA MEDICINE-478, 375 Jackson, St. Paul 55102.

FOR SALE—Fully equipped office (nurse and receptionist) in Tracy, Minn. May move right in to a busy lucrative practice. For complete details, R. O. Schroepel, M.D., Tracy, Minn. 507-629-4211.

FAMILY PRACTITIONER—Minnesota community of 2,000, 55 miles from Twin Cities, needs physician. Retirement leaves one physician in residence. Modern community-owned 30-bed hospital; construction of 55-bed ECF and nursing home to begin in spring. Modern clinic. Progressive community with many young families, offering financial opportunity and the "good life." Contact James Deis, Gaylord, Minn. 55334, phone 612-237-2476 days or 612-237-2870 evenings.

YOUNG family practitioner(s) wanted. Three doctor clinic built 1973 by 30 year old doctor. New hospital in town. 35 miles south Minneapolis. Early partnership. Salary plus incentive bonus. John Berg, M.D., New Prague, Minnesota 56071.

Acute Viral Hepatitis

Patients with acute viral hepatitis occasionally deteriorate rapidly with a so-called fulminant form of the disease. The mortality rate in this situation is at least 80% despite all known forms of therapy. There is now the possibility that treatment with specific antibody to Australia antigen or serum hepatitis-associated antigen (HbAg) may permit survival. Supplies of antibody are limited and its usefulness has not yet been claimed by uncontrolled observations. The National Blood Resource Branch of the National Heart and Lung Institute has initiated a controlled multi-center study to assess the efficacy of such therapy. Dangers associated with the use of antibody therapy, while conceivable, have not been recognized to date.

The Mayo Clinic is participating in this study and is prepared to receive patients with this condition and enter them into the study if they meet certain criteria and provide full consent. A member of the Liver Group at 1-507-282-2511 will be pleased to discuss any patient.

APRIL 1973

Everybody experiences psychic tension.

Most people can handle this tension.

Some people develop excessive psychic tension and need your counseling

and a few may need counseling
and the psychotropic action of Valium® (diazepam).

Before deciding to make Valium (diazepam) part of your treatment plan, check on whether or not the patient is presently taking drugs and, if so, what his response has been. Along with the medical and social history, this information can help you determine initial dosage, the possibility of side effects and the ultimate prospects of success or failure.

While Valium can be a most helpful adjunct to your counseling, it should be prescribed only as long as excessive psychic tension persists and should be discontinued when you decide it has accomplished its therapeutic task. In general, when dosage guidelines are followed, Valium is well tolerated (see Dosage). For convenience it is available in 2-mg, 5-mg and 10-mg tablets.

Drowsiness, fatigue and ataxia have been the most commonly reported side effects.

Until response is determined, patients receiving Valium should be cautioned against engaging in hazardous occupations requiring complete mental alertness, such as driving or operating machinery.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anti-convulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect.

Adults: Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. **Geriatric or debilitated patients:** 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) **Children:** 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 100 and 500. All strengths also available in Tel-E-Dose® packages of 1000.

acute arthritic inflammation...heat that freezes

In acute rheumatoid arthritis consider Tandearil. The anti-inflammatory action of Tandearil quickly helps reduce heat, pain, swelling, and stiffness. Results are usually seen in 3 or 4 days. Try it for a week when the symptoms defy aspirin control.

Remember that Tandearil is not a simple analgesic. It should not be used on patients responding to routine therapy. Before using, please read the prescribing information. It's summarized below.

Tandearil® helps take the heat off oxyphenbutazone NF Geigy

Tablets of 100 mg.

Important Note: This drug is not a simple analgesic. Do not administer casually. Carefully evaluate patients before starting treatment and keep them under close supervision. Obtain a detailed history, and complete physical and laboratory examination (complete hemogram, urinalysis, etc.) before prescribing and at frequent intervals thereafter. Carefully select patients, avoiding those responsive to routine measures, contraindicated patients or those who cannot be observed frequently. Warn patients not to exceed recommended dosage. Short-term relief of severe symptoms with the smallest possible dosage is the goal of therapy. Dosage should be taken with meals or a full glass of milk. Patients should discontinue the drug and report immediately any sign of: fever, sore throat, oral lesions (symptoms of blood dyscrasia); dyspepsia, epigastric pain, symptoms of anemia, black or tarry stools or other evidence of intestinal ulceration or hemorrhage, skin reactions, significant weight gain or edema. A one-week trial period is adequate. Discontinue in the absence of a favorable response. Restrict treatment periods to one week in patients over sixty.

Indications: Acute gouty arthritis, rheumatoid arthritis, rheumatoid spondylitis.

Contraindications: Children 14 years or less; senile patients; history or symptoms of G.I. inflammation or ulceration including severe, recurrent or persistent dyspepsia; history or presence of drug allergy; blood dyscrasias; renal, hepatic or cardiac dysfunction; hypertension; thyroid disease; systemic edema; stomatitis and salivary gland enlargement due to the drug; polymyalgia rheumatica and temporal arteritis; patients receiving other potent chemotherapeutic agents, or long-term anti-coagulant therapy.

Warnings: Age, weight, dosage, duration of therapy, existence of concomitant diseases, and concurrent potent chemotherapy affect incidence of toxic reactions. Carefully instruct and observe the individual patient, especially the aging (forty years and over) who have increased susceptibility to the toxicity of the drug. Use lowest effective dosage. Weigh initially unpredictable benefits against po-

tential risk of severe, even fatal, reactions. The disease condition itself is unaltered by the drug. Use with caution in first trimester of pregnancy and in nursing mothers. Drug may appear in cord blood and breast milk. Serious, even fatal, blood dyscrasias, including aplastic anemia, may occur suddenly despite regular hemograms, and may become manifest days or weeks after cessation of drug. Any significant change in total white count, relative decrease in granulocytes, appearance of immature forms, or fall in hematocrit should signal immediate cessation of therapy and complete hematologic investigation. Unexplained bleeding involving CNS, adrenals, and G.I. tract has occurred. The drug may potentiate action of insulin, sulfonylurea, and sulfonamide-type agents. Carefully observe patients taking these agents. Nontoxic and toxic goiters and myxedema have been reported (the drug reduces iodine uptake by the thyroid). Blurred vision can be a significant toxic symptom worthy of a complete ophthalmological examination. Swelling of ankles or face in patients under sixty may be prevented by reducing dosage. If edema occurs in patients over sixty, discontinue drug. **Precautions:** The following should be accomplished at regular intervals: Careful detailed history for disease being treated and detection of earliest signs of adverse reactions; complete physical examination including check of patient's weight; complete weekly (especially for the aging) or an every two week blood check; pertinent laboratory studies. Caution patients about participating in activity requiring alertness and coordination, as driving a car, etc. Cases of leukemia have been reported in patients with a history of short- and long-term therapy. The majority of these patients were over forty. Remember that arthritic-type pains can be the presenting symptom of leukemia.

Adverse Reactions: This is a potent drug; its misuse can lead to serious results. Review detailed information before beginning therapy. Ulcerative esophagitis, acute and reactivated gastric and duodenal ulcer with perforation and hemorrhage, ulceration and perforation of large bowel, occult G.I. bleeding with anemia,

gastritis, epigastric pain, hematemesis, dyspepsia, nausea, vomiting and diarrhea, abdominal distention, agranulocytosis, aplastic anemia, hemolytic anemia, anemia due to blood loss including occult G.I. bleeding, thrombocytopenia, pancytopenia, leukemia, leukopenia, bone marrow depression, sodium and chloride retention, water retention and edema, plasma dilution, respiratory alkalosis, metabolic acidosis, fatal and nonfatal hepatitis (cholestasis may or may not be prominent), petechiae, purpura without thrombocytopenia, toxic pruritus, erythema nodosum, erythema multiforme, Stevens-Johnson syndrome, Lyell's syndrome (toxic necrotizing epidermolysis), exfoliative dermatitis, serum sickness, hypersensitivity angiitis (polyarteritis), anaphylactic shock, urticaria, arthralgia, fever, rashes (all allergic reactions require prompt and permanent withdrawal of the drug), proteinuria, hematuria, oliguria, anuria, renal failure with azotemia, glomerulonephritis, acute tubular necrosis, nephrotic syndrome, bilateral renal cortical necrosis, renal stones, ureteral obstruction with uric acid crystals due to uricosuric action of drug, impaired renal function, cardiac decompensation, hypertension, pericarditis, diffuse interstitial myocarditis with muscle necrosis, perivascular granulomata, aggravation of temporal arteritis in patients with polymyalgia rheumatica, optic neuritis, blurred vision, retinal hemorrhage, toxic amblyopia, retinal detachment, hearing loss, hyperglycemia, thyroid hyperplasia, toxic goiter, association of hyperthyroidism and hypothyroidism (causal relationship not established), agitation, confusional states, lethargy; CNS reactions associated with overdosage, including convulsions, euphoria, psychosis, depression, headaches, hallucinations, giddiness, vertigo, coma, hyperventilation, insomnia; ulcerative stomatitis, salivary gland enlargement. (B)98-146-800-F (10/71)

more than sleep

YOUR CHOICE OF SLEEP MEDICATION
IS WISELY BASED ON MORE THAN
SLEEP-INDUCING POTENTIAL

Sleep with relative safety

Chronic tolerance studies have confirmed the relative safety of Dalmane (flurazepam HCl); no depression of cardiac or respiratory function was noted in patients administered recommended or higher doses for as long as 90 consecutive nights.

In most instances when adverse reactions were reported, they were mild, infrequent and seldom required discontinuance of therapy. Morning "hang-over" with Dalmane has been relatively infrequent. Dizziness, drowsiness, lightheadedness and the like have been the side effects noted most frequently, particularly in the elderly and debilitated. (An initial dose of Dalmane 15 mg should be prescribed for these patients.)

Sleep for 7 to 8 hours without need to repeat dosage during the night

No sleep medication has been as rigorously evaluated in the sleep research laboratory as Dalmane. Insomnia patients given one 30-mg capsule of Dalmane (flurazepam HCl) at bedtime, on average: fell asleep within 17 minutes, had fewer nighttime awakenings, spent less time awake after sleep onset, and slept for 7 to 8 hours with no need to repeat dosage during the night.

Sleep with consistency— no waning of therapeutic effectiveness

Over multiple nights of therapy, no waning of drug effectiveness was noted. There was consequently no need to increase dosage during the study periods. It stands to reason that the fewer repeat or incremental doses needed to sustain sleep, the lower the total cost of the sleep medication. Consistent effectiveness is the measure of Dalmane (flurazepam HCl) economy.

When your evaluation of insomnia indicates the need for a sleep medication, consider Dalmane—a single entity nonnarcotic, nonbarbiturate agent proved effective and relatively safe for relief of insomnia.

DALMANE®

(flurazepam HCl)

When restful sleep is indicated

One 30-mg capsule h.s.—usual adult dosage.

One 15-mg capsule h.s.—initial dosage
for elderly or debilitated patients.

ROCHE

ROCHE LABORATORIES
Division of Hoffmann-La Roche Inc.
Nutley, New Jersey 07110

Before prescribing Dalmane (flurazepam HCl), please consult Complete Product Information, a summary of which follows:

Indications: Effective in all types of insomnia characterized by difficulty in falling asleep, frequent nocturnal awakenings and/or early morning awakening; in patients with recurring insomnia or poor sleeping habits; and in acute or chronic medical situations requiring restful sleep. Since insomnia is often transient and intermittent, prolonged administration is generally not necessary or

recommended.

Contraindications: Known hypersensitivity to flurazepam HCl.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness (e.g., operating machinery, driving). Use in women who are or may become pregnant only when potential benefits have been weighed against possible hazards. Not recommended for use in persons under 15 years

of age. Though physical and psychological dependence have not been reported, recommended doses, use caution in ministering to addiction-prone individuals or those who might increase dosage.

Precautions: In elderly and debilitated patients, initial dosage should be limited to 15 mg to preclude oversedation, dizziness or ataxia. If combined with other drugs having hypnotic or CNS-depressant effects, consider potential additive effects. Employ usual precautions in patients who are severely depressed, or with

depression or suicidal tendencies. Blood counts and liver and kidney tests are advised during therapy. Observe usual precautions of impaired renal or liver function.

Reactions: Dizziness, drowsiness, lightheadedness, staggering, ataxia have occurred, particularly in elderly or debilitated patients. Severe lethargy, disorientation and possibly indicative of drug intolerance, have been reported.

Also reported were headache, heartburn, upset stomach, nausea, vomiting, diarrhea, constipation, GI pain, nervousness, talkativeness, apprehension, irritability, weakness, palpitations, chest pains, body and joint pains and GU complaints. There have also been rare occurrences of sweating, flushes, difficulty in focusing, blurred vision, burning eyes, faintness, hypotension, shortness of breath, pruritus, skin rash, dry mouth, bitter taste, excessive salivation, anorexia, euphoria, depression, slurred speech,

confusion, restlessness, hallucinations, and elevated SGOT, SGPT, total and direct bilirubins and alkaline phosphatase. Paradoxical reactions, e.g., excitement, stimulation and hyperactivity, have also been reported in rare instances.

Dosage: Individualize for maximum beneficial effect. *Adults:* 30 mg usual dosage; 15 mg may suffice in some patients.

Elderly or debilitated patients: 15 mg initially until response is determined.

Supplied: Capsules containing 15 mg or 30 mg flurazepam HCl.

He won't resist feeling better with **Mylanta[®]**

Because the taste is good.

- ☐ promptly relieves hyperacidity
- ☐ also relieves fullness and bloating
- ☐ non-constipating

President's Letter

Options for the Future

THIS MONTH MINNESOTA MEDICINE previews the 120th annual meeting at the Radisson South in Minneapolis May 24-25, 1973. The scientific program is completed and several specialty societies are meeting in conjunction with the state meeting. The reports of last year's activities are being compiled, resolutions from the delegates, county and specialty societies and committees of the Association are being submitted.

In previous years, approximately a thousand physicians have registered and participated in the annual meeting activities. I hope that number will be significantly increased this year. At no time in the past have as many issues been before us; has medicine been criticized as severely; have there been as many governmental, consumer, media, hospital or insurance groups as outspoken about what they feel are our shortcomings.

The time is now at hand for medicine to take a decisive stand for what is best for medical and health care. What are your views on unionization, strengthening our own society, splintering into specialty groups or special interest groups, national health insurance, Ameriplan, Medi-Credit, the Kennedy Bill, PSRO's, peer review, quality assurance, continuing education? Will we sit back and complain about "organized medicine," the Minnesota State Medical Association or the AMA, or will we strive to weld a common front of excellent physicians improving our individual and collective capabilities for delivering the best medical care?

Do you wish to take part in these decisions? Get your facts and make your voice heard in person or through your delegate to the Minnesota State Medical Association House of Delegates. It's your option. Will you exercise it or are you going to be too busy to take part in shaping your future?

—Y'all Come—

to the Radisson South for the 1973 Annual Meeting

ALL ROADS LEAD to the Radisson South, Bloomington for the annual meeting of the Minnesota State Medical Association. It's the year of enrichment, and on May 24 and 25 the medical doctors of the state will come together to take part in their profession's scientific assembly.

This year, more than ever before, the aim of the program is to aid the physician in his constant effort to update and increase his knowledge of what's new and improved in the world of medicine—and to help him incorporate what he sees, hears, and learns into his daily practice.

On May 24 the scientific sessions evolve from the theme, "Physiology in Daily Practice" and cover the spectrum of life-supporting organs of man.

Getting right to the heart of the matter at 9:00 a.m. on the 24th, doctors will have the opportunity to hear about and discuss the physiology of the heart and developments in the field of cardiac care.

From there, the sessions go on to "The Kidney and Blood Pressure"; "Psychopharmacology and Brain Function" and "Immunology and Infections."

Because the delivery of medical care is the foremost concern of every physician, the program on Friday, May 25, will relate directly to the patient, moving from the 9 a.m. session on "Patient Education; The Basis of Quality Practice" to include, throughout the day, "Children in Trouble"; "Problems of Aging"; "The Personal Life of the Physician"; "Medical, Psychological and Social Hazards of the Abortion;" "Preabortion and Post-abortion Counseling;" and "The Abortion Procedure."

Each session will have a leader experienced and knowledgeable on his subject. As 1973 is the year of the history-making abortion ruling, the last two sessions on Friday, May 25, will be of special interest. Dr. Janc E. Hodgson of St. Paul will speak on the abortion procedure in the first trimester at the final session on Friday, May 25, followed by Robert Goodlin, M.D., Associate Professor of Obstetrics and Gynecology at Stanford University School of Medicine, who will give a presentation on abortion in the second trimester.

There'll Be Business—As Usual

The wheels have been turning to make this, the 120th annual meeting, 120 times more interesting and productive than any other. Committee chairmen have been busy arranging time and place for their meetings. The Physiatriic Society will meet in conjunction with this event on May 26—all day.

Councilors' activities begin at 5:30 p.m. on Tuesday, May 22 and continue on through Friday, May 25, ending in a dinner meeting at 6:30 p.m. The State office will inform councilors of all definite plans and schedules as they develop.

The House of Delegates will hold its first meeting at 1:00 p.m. on Wednesday, May 23. That evening the delegates will join the councilors to call it a day over a dinner buffet. The second session of the House will convene at 1:40 p.m. on Friday, May 25.

There'll Be Exhibits—Better Than Usual

Programs and breaks are planned to give everyone an opportunity to visit the exhibits in the Great Hall East. They'll be open Thursday and Friday, May 24-25 from 8:30 a.m. to 5:00 p.m. See them, too, in the Great Hall Center and the Great Hall Foyer.

There'll Be Breaks In The Motion

Beautiful surroundings and good food will provide pleasant breaks in the days' occupations. Luncheons in the celebrated Tiffany Room on Thursday and Friday; The President's Reception on Thursday in the lovely Garden Court are events to anticipate. And, in a grand climax, the annual banquet will bring together all attending physicians and guests. Among the honored guests of the evening are the physicians who are marking their 50th anniversaries as licensed doctors of medicine. Dinner and dancing, with an air of gracious sociality, will close two days of rewarding and professionally enriching experiences.

There'll Be Auxiliary Meetings

The Woman's Auxiliary will register its members from 5:00 p.m. to 9 p.m. on Wednesday,

May 23, on Thursday, May 24 from 8:30 a.m. to 2:00 p.m., and on Friday, May 25, in the morning, from 8:30 to 11:30.

The Auxiliary's Board of Directors will meet at 9:00 a.m. on Thursday, and they plan their annual meeting for 9:00 a.m. on Friday.

Pleasant breaks for the ladies will include a Sherry Hour and luncheon for board members on Thursday, followed by a tea for all auxiliary members, and their guests, at The Woman's Club of

Minneapolis.

The Camelot will provide the setting for the big annual luncheon from noon to 3:00 on Friday, May 25. Buses will be on hand for transportation. It promises to be the best yet for the Auxiliary in planning, programming, and attendance. No member will want to miss the 120th—The Radisson South in Bloomington, May 24 and 25, 1973.

W. Albert Sullivan, Jr., M.D.
Co-Chairmen

Preliminary Scientific Program Synopsis
May 24 and 25
Radisson South-Minneapolis
May 24: Physiology in Daily Practice

Basic scientists will join with clinical practitioners throughout the day to correlate cellular, organ, and system physiology with the problems met by the doctor in daily practice.

9:00-10:30 *Session I: The Big Heart*

a.m. Session Leader: Carlos E. Harrison, Jr., M.D., Division of Cardiovascular Diseases and Internal Medicine, Mayo Clinic, Rochester

- Normal muscle cell physiology and its alterations in common heart diseases.
- The relationship of cardiac work, ion exchange, myocardial oxygen consumption, and their linkage to cardiac contraction, conduction, and the use of energy
- Congestive failure, valvular disease, septal defect, potassium depletion
- Relationship of cardiac drugs to basic physiology

11:00-12:20 *Session II: Kidney and Blood Pressure*

a.m.-p.m. Session Leader: Cameron G. Strong, M.D., Division of Nephrology and Internal Medicine, Mayo Clinic, Rochester

- The handling of sodium and potassium by the kidney in health and in disease conditions and the relationship of this kidney work to renin and angiotensin production as factors in hypertension
- The handling of sodium in renal insufficiency
- Clinical treatment of hypertension based on physiologic concepts

1.40- 3:00 *Session III: Psychopharmacology and Brain Function*

p.m. Session Leader: Faruk S. Abuzzahab, M.D., Clinical Assistant Professor of Psychiatry, University of Minnesota, Minneapolis

- Advances in chemical, electrical, and circulatory physiology of the central nervous system in normal health and in diseased states: depression, schizophrenia, parkinsonism, and other common diseases
- Choice of drug treatment or other modalities related to physiologic concepts

3.30- 5:00 *Session IV: Immunology and Infections*

p.m. Session Leaders: Charles F. McKhann, M.D., Professor of Surgery, University of Minnesota, Minneapolis and Richard L. Simmons, M.D., Associate Professor of Surgery, University of Minnesota, Minneapolis

- Current concepts of immunology in the understanding and management of stress syndromes, infectious diseases, and some malignant diseases
- Clinical management related to basic physiologic concepts

Infectious Complications

Following Legal Abortion

EMANUEL GAZIANO, M.D.* AND EDWARD L. KAPLAN, M.D.*

RECENT ANALYSES indicate that the rate of early medical complications following legal abortion in the U.S.A. varies from two to almost ten percent depending upon the patient population, the duration of gestation, and the method of termination of pregnancy.^{1,2} Major complications such as uterine perforation, excessive blood loss, and serious pelvic infection have been reported to occur in only 1% or less of legal abortions.² One of the most common complications of legal abortion is the infection-hemorrhage syndrome which is associated with retained infected tissue or endometritis.¹

Minnesota had a restrictive abortion law in that abortions were allowed only when necessary to preserve the life of the pregnant woman.³ It is estimated that each year approximately fifteen hundred to two thousand Minnesota residents sought legal abortions elsewhere prior to the United States Supreme Court decision of 1973.[†] Residents of states with restrictive abortion laws seeking to terminate a pregnancy often had to travel long distances for the procedure. After these procedures are completed the patients are usually observed for a period of hours and then return home. Because of the distances involved and the psychological aspects which often accompany abortion, medical follow-up may not be optimal since the patients could be thousands of miles away from the hospital or clinic where the procedures were performed and may not seek care in their own community following their return. During a four month period (July 13, 1971 through November 11, 1971), 10 patients with

the infection-hemorrhage syndrome following legal abortion performed out of the state of Minnesota were admitted to the Hennepin County General Hospital in Minneapolis. The purpose of this paper is to call attention to the frequency of occurrence of this problem in one general hospital and to present the clinical features, bacteriological data, and management of these patients.

Patient Data

The clinical and bacteriological features of these 10 patients are listed in Table 1.[‡] The patients ranged in age from 15 to 40 years. Eight of the abortions were performed in New York City, one was performed in Canada and the other in Wisconsin. Seven of the patients were primigravid, while one to four pregnancies preceded the abortion in the remaining three.

The length of gestation at the time of abortion varied from seven to 20 weeks (mean = 10.6 weeks). Vacuum aspiration was performed on an ambulatory basis in eight patients: one dilatation and curettage was also performed on an outpatient basis. One pregnancy was terminated with intra-amniotic saline infusion during hospitalization.

Lower abdominal cramping pain, fever, chills and vaginal bleeding were present in all ten patients and usually occurred from two to five days following the procedure. The onset of symptoms occurred 12 hours after abortion in the patient whose pregnancy was terminated with intra-amniotic saline infusion. Vaginal bleeding following the procedure was not excessive in any of the patients, but increasing vaginal flow was often coincident with the development of pelvic pain and fever.

Recorded maximum temperature elevations ranged from 99.6°F. to 103.2°F. As can be seen from Table 1, there was a poor correlation between the highest recorded fever and signs of pelvic tenderness.

All patients exhibited marked pelvic tenderness to palpation while pelvic peritonitis, as manifest

‡See page 271.

by abdominal rebound, was present in seven. Retained infected tissue was present within the uterus in four patients necessitating uterine reevacuation.

Cultures, using sterile cotton swabs, were obtained directly from the endometrial surface of the uterus in all ten patients. Blood cultures were obtained from eight of the ten patients on admission to the hospital. Cultures were incubated aerobically and anaerobically using blood agar, eosin-methylene blue and sodium azide plates, and both trypticase soy broth and thioglycolate broth.

Beta hemolytic streptococci were recovered from the endometrial cultures from three patients (Table 1.) In all three patients, these were reported as pure cultures. These three streptococci were characterized by the bacitracin disc technic as not being Group A, but the strains were unfortunately discarded before serological grouping could be performed. Gram negative bacteria were cultured from the endometrial surface from four patients, but no gram negative organism was isolated in pure culture. *E. Coli* was isolated from four patients, and *Klebsiella-enterobacter* from one patient. An anaerobic streptococcus (not further characterized) was isolated from the endometrial surface of three patients. *Staphylococcus epidermidis* was isolated from the endometrial cultures of six patients. Aerobic gram positive rods (not further characterized) and diphtheroids were each isolated once.

Of the eight patients from whom single blood cultures were drawn, the blood cultures were positive in three (37.5%): non-Group A beta hemolytic streptococcus,* *E. Coli*, and *Staphylococcus epidermidis*. In each patient, the same organism was also recovered from direct cultures from the endometrial surface. Two of the three patients with positive blood cultures had retained tissue in the uterus.

Five of the ten patients received antibiotic prophylaxis at the time of abortion. Three patients were given ampicillin; one received tetracycline, and the fifth, an unknown antibiotic. The specific dosages and duration of administration are unknown, but all were allegedly given orally. Two of the three patients with positive blood cultures had received no prophylaxis. The third patient received oral tetracycline as prophylaxis, yet *Staphylococcus epidermidis* was cultured from both blood and endometrial surface.

*Characterized by the bacitracin disc technic.

All patients were treated with bedrest and parenteral antibiotics, usually either penicillin or one of the cephalosporin group of antibiotics in combination with kanamycin. Antibiotic therapy was altered in some cases on the basis of the clinical response and results of the culture and antibiotic sensitivities. Parenteral antibiotics were then continued until the patient was afebrile at least 48 hours and pelvic tenderness was absent. Seven of the ten patients showed improvement within the first two to three days following therapy. In three patients, either fever or marked tenderness persisted for five to six days. Hospital stay ranged from three to eight days (average = 5.1 days).

Discussion

Nathanson reported an infection rate of fifteen per thousand first trimester ambulatory abortions by the vacuum aspiration method of terminating pregnancy.¹ Tietze reported an incidence of isolated pelvic infection following suction curettage as high as twelve per thousand, an incidence of two per thousand for hemorrhage and infection, and a rate of six per thousand for fever only.² These figures must be considered minimal since follow-up evaluations in both these series were incomplete. This is further suggested by a series from England reporting significant elevation of temperature from almost 30% of women following legal abortion.⁴ Stewart and Goldstein have recently reported a readmission rate of 1.6% following early uterine evacuation.⁵ These authors further suggested that while significant infection (endoparametritis and endometritis) was responsible for almost one-third of these readmissions, additional morbidity may result from post inflammatory tubular obstructions leading to sterility.

The bacteria recovered from these patients are not unexpected ones. Although the beta hemolytic streptococci recovered from the endometrial surfaces of three patients and from the blood of one patient were unfortunately discarded before they could be serologically grouped, these may well have been Group B streptococci since this group of beta hemolytic streptococci is commonly found in the vagina of pregnant women and not infrequently cause serious problems in the neonatal period.^{6,7} However, other serological groups of *Streptococcus pyogenes* (D, F, & G) as well as other streptococci, staphylococci, and coliform and diphtheroid bacilli are considered normal vaginal flora.⁸ Although not specifically studied at the time of abortion, the resemblance of the vaginal

flora to that of the vulva has been noted during the first few days following delivery.⁸ Thus, it is also possible that some of the gram negative organisms recovered from these patients may also have originated from the perineum. The coagulase negative staphylococci frequently recovered from women described in this study might be considered to represent contamination, yet the pres-

ence of the organism in both the blood and endometrial cultures in one patient suggests its pathogenic capacity.

While it is impossible to arrive at an accurate denominator to determine a complication rate, these very serious and potentially fatal complications of legal abortion must also occur with some

TABLE 1
Clinical and Bacteriological Features in Patients with Infection Following Legal Abortion

#Onset of symptoms occurred 12 hours after abortion not 12 hours after infusion of Saline.

frequency in hospitals in other communities throughout this country. While the number of women traveling long distances to other states for legal abortions will be reduced following the recent United States Supreme Court decision, it is likely that travel between rural areas and urban centers for this procedure may not be reduced. Physicians and those persons involved with abortion referral services should be aware of this prob-

lem so that careful medical attention can be given these women after their return to their home community. Hospitals and clinics performing legal abortion must evaluate carefully not only the risks involved in these procedures, such as endometritis and bacteremia, but also the potential latent effects on subsequent pregnancies. Finally, the role of antibiotic prophylaxis in legal abortion should be carefully studied.

Many of our best friends have perished: among these—I grieve for the grief it will give you—Andrew Ammonio, in whom good letters and all good men have suffered a great loss. He thought himself protected against contagion by his temperance in food. It was due to this, he thought, that his whole household escaped, while almost everybody he met had their whole families laid up. He boasted to me and to many others of this, a few hours before he died. For in this Sweating Sickness death always comes, if it does come, on the first day. I, with my wife and children, am as yet untouched: the rest of my household has recovered. I tell you, there is less danger on a battle front than in London. And now, I hear, it is beginning to rage at Calais just as we are being driven there on diplomatic business—as if it were not enough to have lived among infection, but one must follow it when it goes.*

*Thomas More to Erasmus, August 19, 1517.

Veterans Administration

Three young men have completed their training as urological assistants and received certificates from the Minneapolis Veterans Administration Hospital: John Busch, a former Navy medical corpsman, who has started work with a private group of urologists in Mason City, Iowa; Silas Foiles, a former U.S. Army medical corpsman, from LaCrosse, Wis., who will be employed there by a private clinic; and Roger Ordal, Richfield, from the Navy medical corps, who has joined the Trover Clinic in Madisonville, Ky.

The program is the only one of its kind in the state designed to train assistants to the urological physician.

Renal Hamartoma

JOHN A. SOUCHERAY, M.D., HAROLD A. REIF, M.D., AND
CLYDE E. BLACKARD, M.D.

WITH AVAILABLE RADIOGRAPHIC techniques, the diagnosis of renal cell carcinoma is usually not difficult, however, as illustrated by the following case, a benign renal hamartoma can mimic a hypernephroma.

Case Report

A 68-year-old white female was admitted to the University of Minnesota Hospital for evaluation of a pneumonia. Her past history revealed several episodes of cystitis, but on admission, she had no lower urinary tract symptoms. Urinalysis revealed trace albumin and 10 to 15 white blood cells per high power field. The only other abnormal laboratory test was an erythrocyte sedimentation rate of 71. The clinical triad of convulsions, mental deficiency and adenoma sebaceum which characterize tuberous sclerosis was absent.

From the Division of Urology, Department of Surgery, University of Minnesota, Health Sciences Center, Minneapolis, Minnesota.

An intravenous urogram revealed a mass in the upper pole of the left kidney (Figure 1). An aortogram and left selective renal arteriogram demonstrated a mass that consisted of an abnormal vascular pattern with numerous "basketweave" type vessels, puddling of dye and a rapid appearance of the venous phase suggestive of shunting (Figure 2). The radiologic diagnosis was hypernephroma. Studies for metastasis were negative and subsequently a left nephrectomy with en bloc removal of the surrounding fat, including all of Gerota's fascia, and the left adrenal gland was performed. Her recovery was prolonged by severe post-operative tracheal edema which necessitated a temporary tracheostomy. In three and a half weeks she was discharged.

The gross tumor specimen consisted of a 10 centimeter lobulated partly hemorrhagic mass being moderately firm, greasy and yellow in color (Figure 3). It displaced

Figure 1

Figure 2

the pelvis and ureter downward without invasion and compressed surrounding renal substances. In most places it shelled out easily.

Microscopically it consisted mostly of mature fat with angiomatous and leiomyomatous elements (Figure 4). In the more solidly cellular areas there was considerable pleomorphism and moderate mitotic activity which, taken out of context, would suggest a low grade leiomyosarcoma (Figure 5). The final diagnosis was mesenchymal hamartoma (angiomyolipoma) with low grade leiomyosarcoma.

Discussion

The term hamartoma (Gr. hamartia-defect + oma-swelling) was first described by Albrecht in 1904 to describe tumor-like malformations composed of tissues normally present in an organ but abnormal in arrangement, quantity or degree of maturity.¹ Most renal hamartomas are found in patients with tuberous sclerosis where the incidence varies from 50 to 80 percent, and they are usually multiple and bilateral. Patients with single and unilateral hamartomas usually do not have tuberous sclerosis.² The female to male ratio is 2:1 and most are noted between the third and fifth decade.³ The presentation is usually secondary to hemorrhage within or about the tumor which causes flank pain, fever, signs of a renal mass and occasionally hypovolemic shock.⁴ Spontaneous renal rupture without a history of trauma may occur with massive bleeding limited only by Gerota's fascia.⁵ Hematuria, however, is uncommon. In spite of the frequency of hamartomas in patients with tuberous sclerosis most will remain asymptomatic.

Radiographic Findings

The radiographic findings of renal hamartomas may help to differentiate them from hypernephromas, but frequently this distinction cannot be made. The diagnosis of hamartoma is suggested on the KUB and intravenous urogram by the radiolucent appearance of a large amount of fat which is usually present. Also, the tumor tends to infiltrate and enlarge without distortion of the collecting system. Therefore, the soft tissue mass may seem larger than the deformity of the collecting system would suggest.⁴ Hemorrhage into the fat may obscure these signs.

The general angiographic appearance of hamartomas frequently makes it difficult to differentiate them from hypernephromas. Also, the tumor vessels of both respond identically to epinephrine with a lack of vasoconstriction. Viamontem, how-

Figure 3

Figure 4

Figure 5

ever, has noted small arterial aneurysms from the interlobar and interlobular arteries which he feels are in definite contrast to the irregular size and contour of hypernephroma vessels.² He also noted that the venous phase develops normally in hamartoma in contrast to the early appearance seen with hypernephromas. Unless there is a large amount of radiolucent fat it still appears, however, that the pre-operative diagnosis of hamartoma would be difficult to make on solitary or multiple unilateral renal masses.

Pathology

The gross appearance of hamartomas is yellow or yellow-grey with or without areas of hemorrhage and necrosis.⁶ It is variable in size, non-encapsulated, infiltrating and consists of fat, smooth muscle, fibrous tissue and blood vessels. In some, the presence of mitosis and pleomorphism suggests malignancy but metastasis has never been reported.⁷ With this histologic picture they are commonly referred to as angiomyolipomas and have been mistakenly called primary sarcomas of fat or smooth muscle.

Management

Our basic management agrees with that of McCullough and Scott.⁶ If a solid renal neoplasm is found in a patient who does not have tuberous

sclerosis, we believe the safest treatment is radical nephrectomy.

If the patient has tuberous sclerosis and a solitary renal neoplasm, then, careful attention must be given to the pre-operative studies. If they suggest hamartoma, one could do a careful open biopsy of the lesion and frozen section being careful to properly pack off the biopsy site should the lesion be diagnosed as a hypernephroma. If the lesion is a hamartoma, either nothing further need be done or, if feasible a partial nephrectomy conserving as much normal renal tissue as possible can be performed.

If bilateral renal neoplasms are present in a patient with tuberous sclerosis, the probability of hypernephroma is very small. We would tend not to operate on such patients unless there was compelling evidence of hypernephroma or other conditions such as severe uncontrolled hemorrhage existed.

Summary

A case of renal hamartoma has been presented. The features of renal angiomyolipomas are described in conjunction with a discussion of their management and the difficulty in differentiating them from renal cell carcinomas.

Pediatric Nurse Associate Program

The Pediatric Nurse Associate Program (PNA) at the University of Minnesota began in response to the growing need for primary workers in the field of child health care. For several years, the Master's program had been expanding its clinical courses for public health nursing students. Through this experience it became apparent that the Master's program would have to be changed to accommodate a specialty track in child health care. In June, 1971, the School of Public Health was awarded a five-year special training project grant by the Department of Health, Education and Welfare to prepare nurses to assume a primary care role in ambulatory pediatrics.

The program, under the co-direction of Miss Alma Sparrow, Director of Public Health Nursing and Dr. Robert ten Bensel, Director of Pediatric Ambulatory Care at Hennepin County General Hospital, is in its second year of operation. Seven students were certified as PNAs at the end of the nine month program in June, 1972. Thirteen graduate nurse students are currently enrolled.

The objective of this project is to prepare nurses to care for well infants, children and adolescents. The nursing role is best described as interdependent and collaborative with the physician. The nurse assumes responsibility for providing health care to a well population of infants and children.

The curriculum is designed to provide related didactic and clinical experience concurrently. The didactic content is provided by the medical and nursing faculty at the University of Minnesota for three academic quarters. The clinical experience is obtained in one of six pediatric settings—varying from prepaid-private to public ambulatory clinics:

Children's Hospital—Dr. Carolyn Levitt

Group Health East Clinic—Dr. Byron Johnson

Group Health Medical Center—Dr. Stephen Boros and Dr. John Harkness

Hennepin County General Hospital—Dr. John Tobin, Jr.

St. Paul Ramsey Hospital—Dr. Ray Hippchen

University of Minnesota Pediatric Clinic—Dr. Robert Fisch

Wayzata Children's Clinic—Dr. Mitchell Einzig and Dr. Terril Hart

All clinical settings provide physician and nursing faculty to be available to the student.

The specific objectives are to enable the student: (1) to gain knowledge and skill in medical history taking and physical examination so that she can judge the health status of a child; (2) to integrate these skills with interviewing and counselling so that parents and children receive sensitive and intelligent advice and support; (3) to increase her knowledge in the area of normal growth and development so that she is able to provide age and sex appropriate care; (4) to gain a working knowledge of the general field of child health care so that she will regard and uphold high standards of care to infants, children, adolescents and their families.

The 33rd Annual Congress on Occupational Health will be held at The Benjamin Franklin Hotel in Philadelphia, September 17-18, 1973.

Retroperitoneal and Mesenteric Xanthogranuloma

An Unusual Malady

JAMES S. MOORE JR., M.D.* AND CHARLES E. WEIGENT, M.D.†

AN INTERESTING MASS of the retroperitoneal space was described by Oberling in 1935.¹ This lesion, which he termed a "xanthogranuloma" had the characteristics of both an inflammatory mass and a neoplastic process.

Case Report

An 80-year-old white man was seen at Minneapolis Veterans Hospital in May 1971 with a two-day history of mild abdominal pain. Past history included a subtotal prostatic resection for benign hypertrophy and medical management for mild hypertension.

Physical examination disclosed a smooth firm mass fixed in the umbilical region. The mass measured 13 cm in diameter, was slightly tender, but did not pulsate.

Extensive laboratory data including blood sugar, white cell count, serum cholesterol and serum proteins were normal. Urinalysis revealed a mild pyuria and *Proteus mirabilis* was obtained on culture.

Plain films of the abdomen were unremarkable. Upper gastrointestinal series demonstrated displacement of loops of small bowel from the umbilical region (Figure 1). The mucosa appeared normal and no intrinsic pathology was demonstrated. Barium enema was normal. Intravenous urogram excluded a renal mass or displacement but showed evidence of chronic infection of the right kidney.

Pathology Report

At surgery the abdomen was explored through a mid-line incision. An irregularly lobulated, firm, yellow mass was found within the root of the small bowel mesentery (Figure 2). It measured approximately 12cm x 7cm in size. The mass incorporated the large vessels and a resection was not attempted. A biopsy was taken for microscopic examination. The patient tolerated the procedure well.

The biopsy consisted of a piece of yellowish tissue measuring 2.5cm x 1cm x 1cm. An area at one end was more firm and of a pale yellow color in contrast to the more obviously fatty tissue at the other end. Micro-

scopic examination revealed a polymorphous appearance (Figure 3). Collections of histiocytoid cells ("facultative fibroblasts") were seen (Figure 4). These cells generally had oval or reniform vesicular nuclei. The nuclei showed

Fig. 1—Large mass in the midepigastria region is seen displacing bowel loops.

Fig. 4—Histiocytoid cells (facultative fibroblasts) in lesion.

Fig. 5—Margin of lesion with lymphoid follicles and foam cells extending into adjacent fat.

mild pleomorphism and an occasional mitotic figure was found. Rare multinucleated cells were seen. Surrounding and interspersed with these areas were zones of proliferating fibrous connective tissue infiltrated by numerous inflammatory cells and groups of lipid-laden macrophages. Polymorphonuclear leukocytes, lymphoid cells, and collections of plasma cells were seen. Eosinophils were conspicuous by their absence. Some small, thick-walled blood vessels showing prominent endothelial proliferation were noted. About the irregular margin of the lesion, there were some lymphoid follicles and numerous lipid-laden macrophages were seen extending along the septi and within interstices of the adjacent fatty areolar tissue (Figure 5). Fat stains showed the macrophages to be laden with neutral lipid droplets.

Incidence

Including Oberling's original reports¹ approximately twenty-seven cases of xanthogranuloma of this region have been reported in the English literature.²⁻¹¹ The exact number is difficult to determine because of the unpublished reports, foreign reports and duplication of some case reports. Primary tumors of the retroperitoneal space are quite rare and primary benign tumors are even more unusual. A review of the literature reveals that of 213 cases of primary retroperitoneal tumors only 31 were benign.^{12,13,14} No xanthogranulomas were reported. This may be due, in part, to lack of recognition or to confusion regarding the pathologic characteristics.⁹

Supporting this contention is Stout's series of 81 benign primary retroperitoneal and mesenteric tumors of which there were five xanthogranulomas.⁹ Pack's series of 17 benign lesions of this region included three xanthogranulomas. In a series of 44 solid primary tumors of the mesentery reported by Stout, xanthogranuloma accounted for six cases.¹¹ It is interesting to note that in the last two series mentioned above, xanthogranuloma was the second most common lesion.

Pathology

The Armed Forces Institute of Pathology considers this lesion to be a variant of the fibrous histiocytoma group of tumors.¹⁵ This group also includes sclerosing hemangioma, villonodular tenosynovitis and fibrous xanthoma. The common factor in each of these diverse conditions is the histiocyte. As described by Pear,¹⁶ the histiocyte is a multipotential cell which participates in phagocytic activity. When lipids are phagocytized, it becomes a xanthoma cell. The histiocyte may participate in systemic disease (histiocytosis X) or granulomatous reactions (xanthogranulomatous

pyelonephritis), or may produce a localized neoplastic response, (xanthogranuloma, villonodular tenosynovitis).

Originally Oberling¹ considered xanthogranuloma to be a localized extraosseous manifestation of Hand-Christian-Shuller disease. Some support to this theory has been offered by the report of a case of xanthogranuloma associated with eosinophilic granuloma.⁶ Jaffe has demonstrated however, that eosinophilic granuloma heals by resolution and not by transformation into a xanthogranuloma.¹⁷

Electron microscopic studies suggest that the xanthogranuloma is primary a myoangioma, the endothelium of which is abnormally permeable to cells and lipids.⁴ This observation has not yet been confirmed by other investigators.

Others have suggested that the lesion represents basically an inflammatory response since in several instances it has clearly followed a nidus of chronic infection.^{10,18} Xanthogranulomatous pyelonephritis has been shown to follow suppurative processes of the kidney and it has been emphasized that retroperitoneal extension of this process is microscopically similar to primary retroperitoneal xanthogranuloma.¹⁹

Xanthogranulomatous processes have been reported to occur in the lung,²⁰ stomach,²¹ ovary,¹⁸ and colon²² but because of their extreme rarity, they are usually not included in the differential diagnosis of lesions involving these organs.

Diagnosis

The diagnosis of retroperitoneal xanthogranuloma has never been suggested preoperatively. The following may be helpful clues:

1. While primary retroperitoneal processes (including xanthogranuloma) may occur in any age

group, all of the reported cases of primary mesenteric xanthogranuloma have occurred in the older (60-80) age group.^{11,2} Primary solid tumors of the mesentery of the other origins (spindle cell, etc.), on the other hand, tend to occur in a younger group.¹¹

2. Characteristic radiographic finding of the more common mass lesions such as the radiolucency of a lipoma^{23,24} or the "tacked down" appearance of metastatic carcinoma²⁵ are absent.

3. A nidus of chronic infection is present.

Treatment

Treatment has been primarily surgical. However, because of its location, complete removal is often impossible and recurrences are not uncommon.^{7,11,4} Radiation therapy has been attempted in many cases of retroperitoneal xanthogranuloma, including a few in Oberling's original series. Although said to be radiosensitive, poor documentation of dosages and tumor response has made evaluation of this form of treatment difficult. In two recently reported cases an excellent response was obtained using 3700 rads¹¹ and 3950 rads⁸ respectively. In the first case some recurrence of the tumor was noted during the first two years. The patient was free of tumor thereafter.

Summary

Xanthogranuloma of the retroperitoneum and mesentery is a rare tumor, and the radiologist is often called upon for diagnostic assistance. There are no specific or characteristic radiographic signs, but the lesion should be included in the differential diagnosis of solid lesions involving this area, especially in an older patient. In addition, the radiotherapist should be aware of its radiosensitive nature.

Persistent Truncus Arteriosus

Report of Survival to Age of 52 Years

JOHN B. CARTER, M.D.; LEONARD C. BLIEDEN, M.B.,B.Ch. AND
JESSE E. EDWARDS, M.D.

PERSISTENT TRUNCUS arteriosus is a relatively uncommon congenital malformation of the cardiovascular system. In only exceptional cases does the patient survive beyond infancy or childhood. To our knowledge, only six cases have been reported in which survival occurred to or beyond the third decade, the longest survival being to the age of 43 years. We have studied a patient with persistent truncus arteriosus who lived to the age of 52 years. The rarity of this phenomenon serves

as the basis for placing this case on record.

Case Report

Clinical Features

The patient was a 52-year-old, single, semi-invalid, white woman, hospitalized in a state of progressive congestive heart failure. Her medical history was complex. She was not described as having been a "blue baby" and her physical activity reportedly had not been restricted in early years. An episode termed "inflammatory rheumatism" occurred at the age of five years and subsequently the patient remained a semi-invalid.

At the age of 26 years, following an episode of scarlet fever associated with polyarthralgia, persistent deformities of the knees, hips and elbows resulted. Later in that year, an illness considered to be bacterial endocarditis was associated with episodes of cerebral embolism.

Cardiac catheterization and forward angiocardiography

From the Department of Pathology, United Hospitals, Inc.-Miller Division, St. Paul, Minnesota and the Departments of Pathology and Pediatrics, University of Minnesota, Minneapolis, Minnesota.

This study was supported by Public Health Service Research Grant 5 R01 HL05694 and Research Training Grant 5 TO1 HL05570 from the National Heart and Lung Institute.

Fig. 1—*a.* Exterior of heart and great vessels viewed from in front. Arising from the base of the ventricular portion of the heart is a wide single artery representing the truncus arteriosus (Tr.). The aforementioned vessel divides into the aorta (A.) and the pulmonary arterial system (P.). *b.* Interior of right ventricle (R.V.) and great vessels. Above a ventricular septal defect (D.) the truncus (Tr.) arises from both ventricles. The truncus arteriosus branches into the ascending aorta (A.) and into a short pulmonary trunk (P.T.) from which the right (probe) and left (L.P.) pulmonary arteries arise. Thickening of the three cusps of the truncus valve with mild degrees of prolapse.

were performed in 1950 when the patient was 32 years old. The aortic pressure was 140/80 mm., Hg; the right ventricular pressure was 120/0 mm., Hg. The level of oxygen saturation of aortic blood was 78 percent. A forward angiogram revealed passage of opaque material from the right ventricle into the aorta. The diagnosis of ventricular septal defect and overriding aorta was made and the situation was termed, "Eisenmenger complex." Subsequent angiocardiographic studies were not performed. There followed many hospital admissions, including treatment for ulcerative colitis, multiple urinary tract infections and nephrectomy for renal calculi.

Physical examination at the age of 52 years revealed prominent cyanosis, clubbing of the digits and dyspnea at rest. The brachial blood pressure was 150/60; the pulse rate was 92 beats per minute and the rhythm regular. The apical beat was palpated in the left fifth intercostal space in the anterior axillary line. There was a grade II/VI systolic ejection murmur at the left sternal border and a grade I/VI basal diastolic murmur radiating to the apex. There were bilateral pulmonary rales. The liver was enlarged and tender.

The electrocardiogram revealed right ventricular hypertrophy with first degree AV block. The concentration of hemoglobin in the blood was 17.4 gm./100 ml. The thoracic roentgenogram revealed marked cardiomegaly and prominent hilar vessels bilaterally. Infiltrates were present in each lower lung field. Other laboratory studies were noncontributory. In spite of treatment with bedrest and appropriate medication, the heart failure was unrelenting and the patient died three days after admission at the age of 52 years.

Pathologic Findings

Autopsy disclosed the heart to weigh 525

grams. The right ventricle averaged 12 mm. in thickness and the left averaged 16 mm. in thickness. There was a large defect of the superior aspect of the ventricular septum, above which a single arterial vessel (truncus) arose from both ventricles (Figure 1). The truncus valve was composed of three cusps. Each showed moderate thickening and redundancy of tissue with mild prolapse. There were two coronary arteries showing a normal pattern of distribution. The left coronary arterial system originated from the posterior truncal sinus. The width of the single vessel leaving the ascending aorta was 4.2 cm. Approximately 1.5 cm. above the lower level of the truncus valve, the vessel divided into two; the one toward the right continued as the ascending aorta, while the one from the left was extremely short and almost immediately terminated by branching into the left and right pulmonary arteries. The orifice of the common pulmonary trunk measured 3.5 cm. in diameter. The main pulmonary arteries averaged 2.4 cm. in diameter at their origins.

There were two atrioventricular valves, each showing moderate fibrous thickening of the leaflets and chordae. No vegetations or deformities which could be attributed either to rheumatic disease or healed bacterial endocarditis were encountered. Foci of atherosclerosis were present in the aorta and in the major pulmonary arteries and their

Fig. 2—Photomicrographs of pulmonary arterial vessels. (a.) A large muscular artery shows a plexiform lesion. Elastic tissue stain; x 56. (b.) Numerous dilated arterial vessels are characteristic of "dilatation lesions" of hypertensive pulmonary vascular disease, grade V. Elastic tissue stain; x 42.

elastic branches. Small (200 ml.) pleural effusions were present bilaterally. Chronic passive congestion of the spleen and liver was present. The remainder of the findings were nonspecific, save for the solitary left kidney which weighed 295 grams as a result of compensatory hypertrophy.

Histologic examination of the lungs showed hypertensive pulmonary vascular disease, grade V according to Heath and Edwards.¹ This was characterized by the presence of numerous plexiform and angiomatoid lesions (Figure 2). Extensive dilatation of muscular pulmonary arteries was noted. The pulmonary trunk showed an aortic pattern of elastic tissue indicative of pulmonary hypertension from birth.² Extensive atherosclerosis was present in the elastic branches, as were foci of cystic medial necrosis and medial calcification.

The pulmonary parenchyma showed evidence of severe chronic congestion and edema of the alveolar septa secondary to prolonged ventricular failure. Renal histology showed marked and uniform increase in glomerular size and cellularity consistent with glomerular changes in cyanotic congenital heart disease.³

Comment

In general, the prognosis in truncus arteriosus appears to be dependent upon two factors, namely: (1) the presence or absence of pulmonary stenosis and (2) secondary anatomic effects upon the small pulmonary arterial bed.

When no pulmonary stenosis is present, there are large volumes of pulmonary flow with ultimate deleterious effects upon left ventricular compensation. Such patients tend to succumb as young infants.⁴ This applies to the majority of patients with persistent truncus arteriosus. When there is no obstruction to pulmonary flow, the average survival is less than one month.⁴ Death at this early age is usually the result of markedly in-

creased pulmonary blood flow and subsequent left ventricular failure. These cases are types I, II or III,⁵ in which, large, unobstructed pulmonary arteries arise directly from the proximal truncus.

Cases in which there are no pulmonary arteries (type IV) have a somewhat longer average survival of five years. In this situation, pulmonary circulation is through bronchial arteries. These smaller vessels serve as an obstruction to high levels of pulmonary flow.

To our knowledge, only six other cases of persistent truncus arteriosus with survival beyond the third decade have been reported.⁶⁻¹¹ In four of these six, there was no stenosis in the major pathways for the flow of blood to the lungs.^{6-8,11}

In the fifth case,¹⁰ the malformation was of type IV (pulmonary arterial supply by bronchial arteries). The sixth case⁹ showed a large right pulmonary artery, while the left pulmonary artery was absent. The left lung was supplied by a bronchial arterial branch from the aortic arch.

The present case is that of a 52-year-old woman with type I truncus and severe hypertensive pulmonary vascular disease. It is possible that retention of thick-walled, fetal type pulmonary arteries may serve as a protection against excessive pulmonary flow and ensuing heart failure as suggested by Hicken and associates.⁷ The basis for the development of such lesions in some and death in infancy in others is uncertain.

Summary

A case is presented of persistent truncus arteriosus in a woman who died at the age of 52 years which, to our knowledge, is the longest reported survival with this malformation. The literature on long-term survival with persistent truncus arteriosus indicates that six other cases are on record in which the patient lived longer than 30 years.

Juvenile Nasopharyngeal Angiofibroma

ARNDT J. DUVALL III, M.D.;* THOMAS A. CHRISTIANSEN, M.D.* AND SEVERIN KOOP, M.D.*

JUVENILE NASOPHARYNGEAL angiofibroma is an uncommon tumor of the nasopharynx. Although non-metastasizing and histologically benign, it has the capacity for locally destructive growth and fatal hemorrhage. Several hundred cases have been described in the literature, but the exact incidence is unknown. The following case is illustrative of important aspects of this neoplasm.

Case Report

A 15-year-old boy was referred to the University Hospitals in April, 1971, after a biopsy of a left posterior nasal mass showed a nasopharyngeal angiofibroma. Repeated epistaxis and nasal obstruction had been present since November, 1970. The tumor was easily visible in the nose and nasopharynx and a convex mass was palpable in the left cheek. A left serous otitis media was noted secondary to eustachian tube obstruction. Skull Xrays, sinus films, and laminograms of the paranasal sinuses (Figure 1) suggested extensive posterior and lateral extension of the tumor with involvement of the sphenoid, left ethmoidal and maxillary sinuses, and encroachment into the area of the pterygomaxillary fossa. Carotid angiography demonstrated tumor vessels from the cavernous portion of the left internal carotid and ophthalmic arteries, and extensive vascular supply from both external carotids via the internal maxillary arteries (Figure 2).

Estrogen therapy (diethylstilbesterol,† 5 mg t.i.d.) was employed following which the patient was noted to have less bleeding as the tumor regressed in size. After six months the tumor again appeared to be growing, and the patient was readmitted in October, 1971, for surgery. Following a left external carotid artery ligation, the tumor was removed through a tripartite intraoral approach (Figures 3 and 4). The transpalatal, transmaxillary, and retromaxillary dissection provided ideal exposure of a large, lobulated mass in the posterior left nasal cavity, nasopharynx, and sphenoid sinus. A narrow segment passed through the pterygomaxillary fossa and spread into the infratemporal region (Figure 5). It was completely removed with blunt dissection and a blood loss of 2000 cc. The patient has had no recurrence and is free of functional and cosmetic defects.

Discussion

In 1947, Chelius first described a "fibrous nasal polyp which commonly occurs in persons about the time of puberty," and was followed by the report of Gosselin in 1876 who noted a tendency of this tumor to undergo spontaneous regression after sexual maturity.¹ In 1906, Cheveau suggested the name "Juvenile Nasopharyngeal Fibroma,"² and Friedberg³ popularized the term "Angiofibroma" in 1940. The tumor is commonly recognized as a lesion of adolescent males,^{4,5,6} while occasional reports of its existence in females^{7,8,9} and at extremes of life^{8,10,11} are known.

The lesion has also been located as a primary growth in the paranasal sinuses.¹²

Various theories of pathogenesis have been postulated to explain the peculiar occurrence of this neoplasm, including derivation of the tissue from pharyngobasilar fascia and cartilage.^{13,14,15} Perhaps the most intriguing theory is that proposed by Schiff,¹ who felt that the tumor is a growth response to an ectopic focus of vascular tissue distributed as a hamartoma in the nasopharyngeal periosteum during embryologic development. This tissue is likely related to mucosa of the inferior turbinate which has been shown to be responsive to sex hormones, especially during adolescence. Development of this lesion would then begin with the altered pituitary axis and hormonal changes of puberty.

The diagnosis of nasopharyngeal angiofibroma is suggested when a teenage boy presents with nasal obstruction and epistaxis. Conley's¹⁶ analysis of 38 patients showed 90% had unilateral or bilateral nasal obstruction and 70% had a history of epistaxis. Additional findings, suggestive of more advanced disease, are eustachian tube blockage with secondary hearing loss, secondary infection of the paranasal sinuses, and deformity of the cheek, palate and orbit. Eighty-four percent of Conley's patients presented with symptoms in the juvenile age group. The clinical behavior of this tumor is such that symptoms may be minimal if it remains confined to a small area of the nasopharynx without excessive bleeding. The presentation of symptoms in adults may reflect a lack

Fig. 3—Outlines incisions used in surgical approach.

Fig. 4—Indicates extent of surgical dissection on skull model.

of clinically significant growth until later years.

Mirror examination of the nasopharynx usually demonstrates a smooth, nodular, firm mass bulging in one or both sides of the nasopharynx with extension into the nasal cavity.^{9,16} Color varies from grey to purplish-red and there may be ulceration and secondary infection. Attachment of the tumor is usually broad but pedicle growth has been described.^{9,10} These findings in the usual clinical setting are enough to suggest the diagnosis without biopsy. If so, angiography, as with carotid body tumors, may confirm the diagnosis. When tissue is needed, biopsy is best performed in the hospital in anticipation of severe hemorrhage.^{1,9,16} Differentiation from enlarged adenoids or polyps is not difficult on physical findings. Less common lesions likely to be found in this region include the simple fibroma, chordoma, mucous or minor salivary gland tumor, dermoid cysts and teratoma, esthesioneuroblastoma, fibrosarcoma, and carcinoma.^{1,2,9}

Roentgenographic examination is useful not only in the diagnosis of this neoplasm but also in determining the extent of its growth and blood supply. Sinus and skull Xrays will demonstrate soft tissue mass and bony destruction or displacement. Holman and Miller¹⁷ reported anterior bowing of the posterior wall of the maxillary sinus as particularly suggestive of this tumor. Often the full extent of the lesion is underestimated unless laminograms are employed. The assessment of blood supply by angiography may indicate the usefulness of external carotid artery ligation prior to surgical removal. Treatment of the tumor is tempered by the usually accurate assessment that this lesion is a histologically benign neoplasm of

the pubescent period, causing varying symptoms, with a tendency to less activity and spontaneous regression upon attainment of sexual maturity.^{1,9,16,18,19} Many of these tumors probably go completely unrecognized. Some authors^{11,18,19} feel complete spontaneous regression never occurs, and to wait for the expected involution is to invite serious complication. The invasive growth potential and troublesome hemorrhage and nasal obstruction clearly justify removal of these tumors.

In 1948, Martin⁴ reported on 29 cases over a 20-year period. All of his patients were limited to young males, many with the clinical notation of sexual underdevelopment. He concluded that interstitial (radon seed) therapy was of no value if the lesion exceeded 5 cms in size and carried a significant chance of dangerous bleeding both from insertion and tumor necrosis. He did employ radiation with some success but could not define the optimal tumor dose. As little as 1500 rads were shown to cause facial deformity in one case, and he concluded that this form of treatment was best reserved for patients 18 years of age or older. Martin felt surgical exposure was fraught with the potential of dangerous bleeding and afforded poor tumor exposure. He recorded several instances of a decrease in tumor vascularity with androgen therapy and concluded that hormonal and radiation treatment should be considered primary therapy while anticipating possible spontaneous regression.

Several years later, Figi and Davis,⁹ reviewing 114 cases from the Mayo Clinic over a 40 year period found most of their patients had been treated with a combination of surgery and/or radiation and 42 of the 51 cases treated after 1940 included interstitial radiation plus electrocoagulation. In these latter cases they employed such surgical procedures as transpalatal and transantral exposure of the tumor to facilitate electrocoagulation and radon insertion. They commented that radiation treatment, particularly external, carried a risk of damage to growth centers of the face in the younger patient.

In 1959, Schiff¹ reviewed various therapeutic measures and found both local chemical therapy with sclerosing agents and radon application carried a high risk of secondary severe hemorrhage. In his opinion, external radiation was useful but not indicated before full growth of the facial bones. He employed electrocoagulation successfully in treating small recurrences. Schiff advanced the

Fig 5—Characteristic tumor lobulations: Sphenoid (S); Nose (N); Nasopharynx (NP); Pterygomaxillary Fossa (PT); Infratemporal Fossa (IT).

knowledge of the hormonal relationships of this tumor and demonstrated microscopic and clinical evidence of decreased tumor vascularity with estrogen therapy. He found a similar but less dramatic response with testosterone. He concluded, however, that there was no substitute for surgical extirpation. Interestingly, Schiff noted that three-quarters of his patients were red-haired, a finding increasingly recognized at our institution.

In 1965, Apostol and Frazell²⁰ continued the survey of this lesion at the Memorial Center in New York that had earlier been reported by Martin. Again they found universal occurrence in adolescent males and went so far as to suggest chromosome studies for those females reportedly afflicted by this tumor. They noted that only one of Martin's patients treated with testosterone showed clinical evidence of tumor regression. The behavioral side effects of this drug prompted its deletion from further use at that institution. They found no relationship between the age of onset and symptomatology, and could find no clinical or laboratory evidence for sexual underdevelopment. Their follow-up of those tumors treated by radiation indicated temporary regression of the lesion with significant morbidity and one long-term example of post-radiation induced carcinoma. They employed estrogen therapy as a useful pre-operative means of decreasing tumor vascularity, and felt surgical therapy was the most useful primary means of treatment. Conley¹⁶ is in agreement with this and cited several serious complications of radiotherapy including radionecrosis of the maxilla requiring maxillectomy and post-radiation induced squamous cell carcinoma of the face and orbit. He also could find no evidence of endocrine disturbance.

Surgical Approach

A comprehensive surgical armamentarium is mandatory to effectively treat these tumors. We advocate a tripartite approach. Lesions confined to the nasopharynx are well exposed from a *transpalatal approach*, as are extensions into the sphenoid sinus and posterior choanae. Almost invariably the major blood supply to such tumors is from the internal maxillary artery. Angiography confirms which side affords the chief vascularity. It is then useful to employ transantral (*transmaxil-*

lary approach) ligation of the internal maxillary artery in the pterygomaxillary fossa. The Caldwell-Luc antrostomy can be extended through the lateral nasal wall (Denker modification), for exposure of tumor residing in the more anterior nasal cavity or ethmoids.

Lateral tumor extension into the cheek, as in the case presented, is not unusual and is the most difficult to remove. Proponents^{21,22,23,24} of external incisions in the face or neck are countered by others^{25,26,27} preferring additional intraoral exposure. The *retromaxillary approach* to the pterygoid plates and pterygopalatine fissure is unsurpassed for exposure and minimal morbidity. In these situations where the internal maxillary artery is obscured by tumor, ligation of the external carotid artery may be elected.

Each of these three approaches may be used separately or in combination depending upon the location and extent of the tumor. In some situations the addition of cryosurgery has been helpful.^{11,26} We routinely use estrogens for pre-operative shrinkage of the tumor blood supply. This has been confirmed by obtaining repeat angiograms following hormone administration. Continued hormone therapy and radiation may prove helpful in the event the tumor is unresectable.

Pathology

Sternberg⁶ has reviewed the pathology of those cases from the Memorial Center previously reported by Martin⁴ and Apostol.²⁰ The vascular network displays venules and capillaries of varying caliber with a distinctive lack of elastic tissue and usually only a simple endothelial lining. The capillary bed often directly opposes the intact surface epithelium, explaining propensity to bleed. The epithelium is largely respiratory except in areas of ulceration or squamous metaplasia, and as the tumor expands a pseudocapsule may be formed. The connective tissue stroma is made up of fine and coarse collagenous fibrils interweaving in an irregular manner. Sternberg believes the stellate shape of the stromal cells is characteristic and that the histology of this neoplasm is quite distinctive. McGavran,⁵ utilizing the electron microscope, noted intranuclear dense bodies in these stromal cells or fibrocytes which he feels are unique to this particular tumor.

Tracheobronchial Lavage in Small Infants

MARTHA BURKE-STRICKLAND, M.D.*

THOUGH TRACHEOBRONCHIAL LAVAGE is recommended in the management of adult lung disease,^{1,2} there has been little documentation of its use in small infants and children. While impedance to flow offered by the small bronchioles of children may preclude use of tidal lavage of the whole lung,³ there are many situations in which lavage of just the trachea and large bronchi may be helpful. Results of studies on three infants presented indicate that lavage of the trachea and bronchi with small quantities of saline may be used without significantly impairing ventilation of the infant.

Case Reports

Case 1

The patient was a 5 kg, three month hydranencephalic male infant with bronchitis. His temperature had ranged from 100° to 102°F rectally for eight days. Thick tenacious secretions were poorly handled with a resulting cough that often ended in gagging and vomiting. Coarse shifting rhonchi were heard bilaterally. The chest Xray showed slight increase in markings in the right upper lung field. Xenon 133 studies of pulmonary function showed some possible air trapping in this same area; however, the radiologist felt that slow injection of the Xenon may have produced this as artifact. Baseline arterial blood studies obtained while the infant was breathing air and after 15 minutes of 100% oxygen are summarized in Table 1. He was then intubated, suctioned to remove loose secretions and the tracheobronchial tree lavaged with saline. On the first wash, 10 ml of saline were injected into the endotracheal tube per syringe and needle. A #8F catheter was then inserted and suction applied. Though only five to 10 seconds elapsed, only 2 ml of saline were recovered. On the second and third wash the saline was injected per catheter. Using the same syringe and catheter, withdrawal suctioning was begun at the same instant injection was complete. Recovery was 7.5 and 8 ml respectively. It was estimated that 12-13 ml of saline had been left in the lungs by the three washes. Much thick white mucus was removed by suctioning and spontaneous coughing after the lavage.

Repeat blood studies immediately after the lavage, while he was breathing room air, showed a decrease in

the pO_2 as well as a decreased response to breathing 100% oxygen (Table 1). There appeared to be no inhibition to blowing off CO_2 since both pH and pCO_2 reflected the hyperventilation of crying. Chest sounds were improved, follow up Xenon studies 45 minutes after lavage showed no air trapping, and the conventional chest Xray remained unchanged.

Cultures of saline recovered from the lavage grew out alpha streptococci and pneumococci. A simultaneous nasopharyngeal culture yielded "normal flora" and culture of a needle biopsy of the right upper lobe was negative. There were no apparent complications from the needle biopsy⁴ or the saline lavage. Though no antibiotics were given, clearing the airway of its tenacious secretions appeared to improve his well-being. His temperature abated and recovery was complete within another week.

Though saline lavage did seem to facilitate removal of large quantities of mucus with no clinical cyanosis or air trapping in this first infant, he did suffer a transitory drop in pO_2 . The decrease was not significant in this instance since the arterial pO_2 did not drop below the safe level of 40 mm Hg. Such a decrease in ventilation could have devastating consequences when added to a more seriously compromised lung function, although it is just such infants in the delivery room or newborn intensive care unit that need the tracheobronchial lavage. In this infant, poor recovery of saline initially had left a residual equal to 8% the infant's estimated lung volume.⁵ It was felt that the improved recovery of saline offered by the modification of technique would minimize the risk of even transitory depression of ventilation by residual saline in the lungs. Studies in the other two tends to confirm this impression.

Case 2

The patient was a 1,700 gram male premature transferred to the newborn intensive care unit at 40 hours of age with moderately severe respiratory distress syndrome. With continuous positive pressure breathing (CPPB) respirator assistance and 90% oxygen his blood pH was 7.28, pCO_2 55 mm Hg and pO_2 58 mm Hg. At 47

See editorial, page 299.

hours he suffered severe shock and cardiac arrest when tension pneumothorax developed bilaterally. Resuscitation was successful and relief of the pneumothorax was obtained with closed chest tube drainage. Following this episode, chest Xray showed increased opacification. Resolution was slow and complicated by congestive heart failure and recurrent inspissation of secretions after extubation. Early failure was heralded by an enlarging liver on the sixth day. Response to lanoxin was poor and by the seventh day he had a gallop rhythm, loud ductus murmur and dependent edema. Lasix and an increased dose of lanoxin gave some response; however, he was not considered out of failure for another five days. Several times during these precarious days, his condition appeared further compromised by secretions that could not be removed by chest percussion, postural drainage and suctioning. The blood studies before and after lavage on these occasions are recorded in Table 2. In this infant each lavage procedure consisted of three washes of three ml each. There was a drop in pO_2 after the second lavage as well as increased cloudiness on chest Xray. Clinically his color remained good during the procedure and his respirations were less labored after the lavage. This episode occurred on the day that congestive heart failure was at its worst. Also, in reviewing the situation, it was learned that the revised technique had not been used for injecting and removing the saline. Recovery of saline was only 30% leaving behind about six ml or 6% of the estimated lung volume. In the other instances when the revised technique was used and recovery of saline 70-80%, all parameters showed improvement after lavage. The residual amount of saline left in the lung on these occasions was estimated to equal about 3% of the lung volume.

Early cultures taken from the pharynx and saline retrieved from tracheal lavage both grew out coagulase negative staphylococcus. Dicloxacillin 200 mg/kg was started. By the fifteenth day, the recurring right upper

lobe atelectasis secondary to inspissated secretions was responding to percussion, postural drainage and suctioning. No more lavages were performed. Recovery proceeded uneventfully.

Case 3

The patient was an 1,890 gram meconium stained premature whose Apgars of six and four at birth were followed by grunty, rapid respirations and cyanosis. By the time he was transferred to the intensive care unit at nine hours of age his chest Xray was completely opacified. During the course of CPPB therapy he developed a tension pneumothorax requiring closed chest tube drainage. An ambient oxygen above 40% was required for four days, and the expected bronchopulmonary dysplasia developed during his recovery phase. The attendant scanty production of thick viscid mucus led to recurrent plugging of the bronchi and bronchioles that did not respond to ordinary tracheobronchial toilet and suctioning care. Table 3 summarizes the blood studies immediately before and after lavage on four different days. Recovery of three ml portions of saline x3 was 70-80% on each occasion using the technique of lavage as outlined. Much thick white tenacious mucus was obtained at suctioning during and after lavage. With $F_{I}O_2$ remaining the same, the blood pO_2 improved on each occasion after lavage. Residual amount of saline left in the lungs on each occasion was estimated to be equal to 3-4% of lung volume.

Cultures of saline aspirated at the fourth lavage grew coagulase negative staphylococcus (the first three were negative). This responded to methicillin. While the infant continued to need a moderately increased $F_{I}O_2$ for several weeks, secretions appeared adequately handled without further lavage.

Discussion

Tracheobronchial lavage with saline appeared to facilitate removal of inspissated secretions in

TABLE 2
Studies Before and After Lavage of Case 2

		Blood			Xray after lavage	Condition after lavage
		pH	pCO_2	pO_2		
Day 6	Before Lavage	7.34	57	53	Improved	Large amounts of secretions removed, respirations easier, chest sounds improved
	After Lavage	7.37	57	84		
Day 7	Before Lavage	7.29	63	80	Worse	Large amounts of secretions removed, much improved
	After Lavage	7.37	57	58

	After Lavage	7.50	33	125		
Day 10	Before Lavage	7.28	72	28	Reexpansion of RUL	Improved. Large amounts of secretions removed
	After Lavage	7.37	57	40		
Day 13	Before Lavage	7.29	46	31	Reexpansion of RUL	Large amounts of secretions removed, slight duskiness for two to three minutes. No change in heart rate.
	After Lavage	7.38	35	82		

all three infants. Safety of the procedure, particularly for the more critically ill infant, seems to hinge on the amount of saline left behind in the lung. *When the time delay in initiating suctioning to remove the saline was eliminated, recovery was 60 to 80% of the portion injected.* If the total volume of saline left behind did not exceed 3-4% of the estimated lung volume, there was no apparent decrease in effective ventilation even in the presence of congestive failure.

TABLE 3
Blood Studies on Case 3

Before Lavage			After Lavage		
pH	pCO ₂ mm Hg	pO ₂ mm Hg	pH	pCO ₂ mm Hg	pO ₂ mm Hg
1) 7.3	46	70	7.33	42	105
2) 7.32	51	89	7.31	48	111
3) 7.26	51	53	7.29	52	64
4) 7.29	40	81	7.30	34	103

The technique of lavage as finally evolved appeared to yield beneficial assistance in removal of inspissated secretions as well as achieve the rapid removal of saline necessary for the procedure to be safe. More extensive use of this same technique in management of meconium aspiration syndrome is reported separately.⁶ It has also been used in infant aspiration of formula and medications.

Procedure

Recommended technique for tracheobronchial lavage in small infants:

1. The baby is intubated with a straight walled tube per the orotracheal approach. The lumen of the adapter and the endotracheal tube should be large enough to accept an 8F suction catheter. Only infants under 1,000 grams require a smaller tube and use of a 5F catheter. Maintain sterile technique.

2. 2-5 cc sterile 0.9% NaCl solution *containing no preservatives* is injected per catheter into the endotracheal tube. Immediate suctioning is applied using the same syringe that was used for injection. After the saline has been recovered from the trachea and bronchi, the catheter is removed and oxygen is given by mask over the face for five to 10 seconds.

3. The injection-suction-oxygen cycle is repeated two to three times or until the aspirated material returns clear.

4. Hydrocortisone 1-5 mg/ml may be added to the lavage solution for topical anti-inflammatory effect.

If the team is prepared, a wash-out of three to four cycles can be completed in 90 seconds. No positive pressure ventilation assistance is used if the heart rate remains above 100/minute and the baby maintains a good pink color. If the heart rate drops or the infant is dusky, assistance with a bag resuscitator or a respirator and 100% oxygen is given until the color and heart rate are back to normal.

Meeting

Fourth National Congress on Medical Ethics will be held on April 26-28, 1973 at the Washington Hilton Hotel in Washington, D.C. Contact: Walter H. Judd, M.D., Chairman, Judicial Council, American Medical Association, 535 North Dearborn Street, Chicago, Illinois 60610.

Packed Red Blood Cells

Clinical Uses

JEFFREY McCULLOUGH, M.D.*

TRANSFUSION OF BLOOD products should be undertaken only after considering the etiology and course of the patient's disease. Often the patient does not require whole blood transfusion but only one of its components. The patient is best served when his specific blood deficits are identified and specific replacement therapy is used. In order to use any blood component wisely the physician should be aware of its composition.

Composition of Packed Red Cells

During collection whole blood is made unphysiological by the addition of the citric acid, sodium citrate and dextrose in the anticoagulant solution. If blood is studied immediately after collection, the glucose is increased, the pH is decreased (because of the citric acid) and the sodium is slightly increased (from the sodium citrate). During storage, metabolic changes continue because red cell glycolysis continues although at a subnormal rate. Glucose levels fall (Table 1), because glucose is

utilized in red cell glycolysis. Lactic acid and organic phosphates accumulate, producing further acidity. The red cell membrane is not normally maintained, allowing sodium to move intracellularly from the plasma. Potassium moves from the red cell to the plasma, and plasma potassium rises. Ammonia accumulates as a result of red cell metabolism. Thus, the plasma component becomes increasingly unphysiological and may constitute a hazard to many patients. This risk is minimized by removing the plasma before transfusion.

By converting whole blood to packed red cells, about two thirds of the plasma becomes available for the preparation of cryoprecipitate, fresh frozen plasma, albumin, fibrinogen, gamma globulin, and platelet concentrates. The volume of the unit is decreased by about 200 ml and the hematocrit is increased to approximately 70 percent (Table 2). However the red cell mass and total hemoglobin in the packed red cell unit remain unchanged from whole blood. The total protein, albumin,

Protein Antibodies	Maximal	Minimal

*From Physician's Handbook of Blood Component Therapy. American Association of Blood Banks, Chicago, Illinois, First Edition, 1969.

and globulin are also decreased in the packed red cell unit. However this difference in protein content would not affect the recipient's serum protein concentration. Other changes when whole blood is converted to packed red cells include a decreased amount of citrate, which must be metabolized by the liver, and the removal of approximately 30 mEq of sodium. If the plasma is removed just prior to transfusion, there will be an additional loss of 10 mEq of potassium and a decrease in the total amount of acid and ammonia present. There is a decrease in the total amount of antibody and the soluble antigen present in the packed red cell unit.

Clinical Indications

One of the most important differences between whole blood and packed cells is the decreased volume. Thus packed red cells are specifically indicated for patients in whom fluid overload is a potential problem. Patients with congestive heart failure, elderly or debilitated patients who will not tolerate rapid shifts in intravascular volume, and patients with renal or hepatic failure may all benefit by the reduced volume of packed red cells.

In addition to the reduced volume, packed red cell units have decreased amounts of albumin and sodium. This is an added advantage for patients with problems of fluid overload, because of the tendency of albumin and sodium to draw water into the intravascular space.

If the plasma is removed just prior to transfusion, a unit of packed red cells has up to 10 mEq less potassium than whole blood; therefore, packed red cells are indicated for patients with hyperkalemia. The decreased total amount of acid makes packed red cells ideal for patients with acidosis. Hyperkalemia and acidosis often occur together in patients with chronic renal disease, but the value of packed red cells applies to any patient with either acidosis or hyperkalemia. The decreased amount of ammonia in the packed red cell unit is of benefit to patients with liver failure and/or hepatic coma. Since the amount of red cell antibodies in the packed cell unit is decreased, there is less danger of a severe transfusion reaction when ABO incompatibility exists between the donor's plasma and the recipient's red cells.

The general types of situations which require transfusion are: (1) stable chronically anemic patients, (2) priming of medical instruments, (3) general surgery and (4) acute massive blood loss

stable, chronically anemic patients such as those with depressed erythropoiesis, low grade decompensated hemolysis or slow blood loss require red cells, not volume replacement. The patients usually do not require sodium or potassium or citrate replacements, *only red cells*; and should be transfused with packed red cells.

Priming of heart lung instruments, dialysis instruments and other machines is becoming less of a problem; however, packed cells and saline serve this purpose equally as well as whole blood.

The use of packed red cells in routine surgical procedures has created much more debate than any of the above situations. Schorr and Marx¹ report the use of packed red cells in "routine" surgery, which included 985 procedures ranging from hysterectomy and cholecystectomy to multiple trauma and open heart surgery. During a two year period, 3850 units of packed red cells and 1858 units of whole blood were transfused. The authors concluded that "during the six years this practice has been in effect, there has been no suggestion of increased intraoperative or postoperative morbidity or mortality which could be related to the use of packed red cell transfusions."

Rush and Stewart² replaced blood loss during surgery with Hartmann's Solution until the hematocrit fell to 28-30%. They found, "no detriment to the patient's clinical state," but the blood consumed per patient admission fell 35 percent, the average amount of blood used by the surgical service decreased 320 ml per surgical procedure, and the use of single unit transfusions decreased 47 percent.

Although there are few other clinical reports concerning the use of packed red cells for routine surgery, there are many reports concerning the treatment of shock with solutions other than whole blood. Rigor, et al.³ found neither unexpected complications nor prolonged hospitalizations in 100 patients with an operative blood loss greater than 1000 ml if all of the blood loss was replaced with Hartmann's solution. Golub, et al.⁴ studied thirteen Jehovah's Witness patients who had massive surgery with blood loss approximating 40 percent of their original blood volume, and concluded that up to 1200 ml of blood loss could be replaced by crystalloid solutions alone. Moss, et al.⁵ showed that baboons which were put into shock by acute blood loss had no difference in mortality when the blood loss

was replaced by either normal saline, five percent albumin and saline, or whole blood. Thus, the loss of up to two units of blood during surgery may not require replacement with blood. We suggest that when blood replacement is necessary during surgery, the first two units be administered as packed red cells.

Acute massive blood loss is the only situation in which whole blood probably is superior to packed red cells; even this can be debated. Moss, et al.⁶ have shown that frozen red cells (which are essentially packed red cells) were equally as effective as whole blood in treating 36 acutely injured Viet Nam battle casualties. In fact, Vogel and Vogel⁷ have suggested that 80-90% of all transfusions could be given as packed red cells.

Administration of Packed Red Cells

Many physicians hesitate to order packed red cells because, due to the viscosity, they may be more difficult to administer than whole blood. This problem can be alleviated by using a large bore needle (at least 19 gauge) for administration and thoroughly mixing the packed red cell unit

every twenty minutes to prevent the red cells from accumulating at the bottom of the bag. Normal saline can be added to the packed cell unit during administration by using a Y set. The pore size and surface area of the blood filter are also important: one blood filter (Fenwal FT 293) has significantly more surface area and should facilitate the administration of packed red cells.

Conclusion

There are many situations in which packed red cells can be used, such as transfusion of stable chronically anemic patients and many cases of routine surgery. Specifically there are situations in which packed red cells *should* be used, as they are a superior product and the patient receiving whole blood is receiving a poorer form of therapy. Examples of these specific situations include congestive heart failure, chronic renal disease and hepatic coma. Furthermore, if transfusions were given as packed red cells, plasma would be available for the production of other blood components. Replacement of acute massive blood loss is the major indication for whole blood transfusion.

A DOUBLE-DUTY DIURETIC

DYAZIDE[®]

Each capsule contains 50 mg. of Dyrenium[®] (brand of triamterene)
and 25 mg. of hydrochlorothiazide.

GETS THE WATER OUT IN EDEMA

BRINGS DOWN BLOOD PRESSURE IN HYPERTENSION^{*}

SPARES POTASSIUM IN BOTH

Before prescribing, see complete prescribing information in SK&F literature or *PDR*.

***Indications:** Edema associated with congestive heart failure, cirrhosis of the liver, the nephrotic syndrome; steroid-induced and idiopathic edema; edema resistant to other diuretic therapy. Also, mild to moderate hypertension.

Contraindications: Pre-existing elevated serum potassium. Hypersensitivity to either component. Continued use in progressive renal or hepatic dysfunction or developing hyperkalemia.

Warnings: Do not use dietary potassium supplements or potassium salts unless hypokalemia develops or dietary potassium intake is markedly impaired. Enteric-coated potassium salts may cause small bowel stenosis with or without ulceration. Hyperkalemia (> 5.4 mEq/L) has been reported in 4% of patients under 60 years, in 12% of patients over 60 years, and in less than 8% of patients overall. Rarely, cases have been associated with cardiac irregularities. Accordingly, check serum potassium during therapy, particularly in patients with suspected or confirmed renal insufficiency (e.g., elderly or diabetics). If hyperkalemia develops, substitute a thiazide alone. If spironolactone is used concomitantly with 'Dyazide,' check serum potassium frequently—both can cause potassium retention and sometimes hyperkalemia. Two deaths have been reported in patients on such combined therapy (in one, recommended dosage was exceeded; in the other, serum electrolytes were not properly monitored). Observe patients on 'Dyazide' regularly for possible blood dyscrasias, liver damage or other idiosyncratic reactions. Blood dyscrasias have been reported in patients receiving Dyrenium (triamterene, SK&F). Rarely, leukopenia, thrombocytopenia, agranulocytosis, and aplastic anemia have been reported with the thiazides. Watch for signs of impending coma in acutely ill cirrhotics. Thiazides

are reported to cross the placental barrier and appear in breast milk. This may result in fetal or neonatal hyperbilirubinemia, thrombocytopenia, altered carbohydrate metabolism and possibly other adverse reactions that have occurred in the adult. When used during pregnancy or in women who might bear children, weigh potential benefits against possible hazards to fetus.

Precautions: Do periodic serum electrolyte and BUN determinations. Do periodic hematologic studies in cirrhotics with splenomegaly. Antihypertensive effects may be enhanced in postsympathectomy patients. The following may occur: hyperuricemia and gout, reversible nitrogen retention, decreasing alkali reserve with possible metabolic acidosis, hyperglycemia and glycosuria (diabetic insulin requirements may be altered), digitalis intoxication (in hypokalemia). Use cautiously in surgical patients. Concomitant use with antihypertensive agents may result in an additive hypotensive effect.

Adverse Reactions: Muscle cramps, weakness, dizziness, headache, dry mouth; anaphylaxis; rash, urticaria, photosensitivity, purpura, other dermatological conditions; nausea and vomiting (may indicate electrolyte imbalance), diarrhea, constipation, other gastrointestinal disturbances. Rarely, necrotizing vasculitis, paresthesias, icterus, pancreatitis, and xanthopsia have occurred with thiazides alone.

Supplied: Bottles of 100 capsules.

SK&F CO.

Carolina, P.R. 00630

a subsidiary of Smith Kline & French Laboratories

What's in it for her?

All steroid molecules are not the same...in their activity. In prescribing birth-control pills, estrogen/progestogen activity is more important than milligrams. The woman's hormone profile often indicates the activity best for her.

ethinyl estradiol/50 mcg.

mestranol/100 mcg.

eth
diacetate

ethynodiol diacetate/1 mg.

Typical characteristics of the "balanced" profile

- normal menses
- well-rounded breasts
- clear complexion
- normal figure with normal secondary sex characteristics
- normal cytohormonal pattern

This "center spectrum" pill has had excellent user acceptance for over seven years.

Typical characteristics of the slightly hyper-estrogenic profile

- heavy flow
- large breasts, sometimes fibrotic; nipples well pigmented
- very feminine appearance; occasionally short
- premenstrual syndrome, fluid retention
- tendency to uterine fibroids
- high pyknotic index

This formulation, which has less estrogenic activity than a moderate progestogen dominance, may be a good beginning.

Ovulen®

Available in 20-, 21- and 28-pill schedules
Each white tablet contains: ethynodiol diacetate 1 mg./mestranol 0.1 mg.
Each pink tablet in Ovulen-28® is a placebo containing no active ingredients

for the majority of women...
when centrally balanced
activity is preferred

**Typical characteristics
of the hypogestrogenic
or androgenic profile**

- scanty menses
- small breasts
- thin, often tall,
sometimes asthenic
- possibly masculine
appearance
- acne, hirsutism
- low sexual motivation
- thin vaginal lining,
tendency to vaginitis
and dyspareunia

This pill has a relatively
weak and unique* progestogen
with inherent estrogenicity.
Clinically, just as in animal
studies, it appears not to
possess antiestrogenic and
androgenic activity.

Enovid-E[®]

Available in 20- and 21-pill schedules
Each tablet contains: norethynodrel
2.5 mg./mestranol 0.1 mg

a clear choice for women
when estrogen dominance
and no androgenic activity
are preferred

*Of all the progestogens, norethynodrel
most resembles the molecular structure of
the estrogens. It has the weakest proges-
tational activity of any progestogen in a
combination pill.

Demulen[®]

Available in 21- and 28-pill schedules
Each white tablet contains: ethynodiol
ate 1 mg./ethinyl estradiol 50 mcg.
Each pink tablet in Demulen-28[®] is a
placebo containing no active ingredients.

suited to most women
in low estrogenic activity
moderate progestogen
estrogen dominance are preferred

Ovulen®

Each white tablet contains:
ethynodiol diacetate 1 mg./mestranol 0.1 mg.

Each pink tablet in Ovulen-28® and Demulen-28® is a placebo, containing no active ingredients.

Actions—Ovulen and Demulen act to prevent ovulation by inhibiting the output of gonadotropins from the pituitary gland. Ovulen and Demulen depress the output of both the follicle-stimulating hormone (FSH) and the luteinizing hormone (LH).

Special note—Oral contraceptives have been marketed in the United States since 1960. Reported pregnancy rates vary from product to product. The effectiveness of the sequential products appears to be somewhat lower than that of the combination products. Both types provide almost completely effective contraception.

An increased risk of thromboembolic disease associated with the use of hormonal contraceptives has now been shown in studies conducted in both Great Britain and the United States. Other risks, such as those of elevated blood pressure, liver disease and reduced tolerance to carbohydrates, have not been quantitated with precision.

Long-term administration of both natural and synthetic estrogens in subprimate animal species in multiples of the human dose increases the frequency of some animal carcinomas. These data cannot be transposed directly to man. The possible carcinogenicity due to the estrogens can be neither affirmed nor refuted at this time. Close clinical surveillance of all women taking oral contraceptives must be continued.

Indication—Ovulen and Demulen are indicated for oral contraception.

Contraindications—Patients with thrombophlebitis, thromboembolic disorders, cerebral apoplexy or a past history of these conditions, markedly impaired liver function, known or suspected carcinoma of the breast, known or suspected estrogen-dependent neoplasia and undiagnosed abnormal genital bleeding.

Warnings—The physician should be alert to the earliest manifestations of thrombotic disorders (thrombophlebitis, cerebrovascular disorders, pulmonary embolism and retinal thrombosis). Should any of these occur or be suspected the drug should be discontinued immediately.

Retrospective studies of morbidity and mortality conducted in Great Britain and studies of morbidity in the United States have shown a statistically significant association between thrombophlebitis, pulmonary embolism, and cerebral thrombosis and embolism and the use of oral contraceptives. There have been three principal studies in Britain¹⁻³ leading to this conclusion, and one⁴ in this country. The estimate of the relative risk of thromboembolism in the study by Vessey and Doll³ was about sevenfold, while Sartwell and associates⁴ in the United States found a relative risk of 4.4, meaning that the users are several times as likely to undergo thromboembolic disease without evident cause as nonusers. The American study also indicated that the risk did not persist after discontinuation of administration and that it was not enhanced by long-continued administration. The American study was not designed to evaluate a difference between products. However, the study suggested that there might be an increased risk of thromboembolic disease in users of sequential products. This risk cannot be quantitated, and further studies to confirm this finding are desirable.

Discontinue medication pending examination if there is sudden partial or complete loss of vision, or if there is a sudden onset of proptosis, diplopia or migraine. If examination reveals papilledema or retinal vascular lesions medication should be withdrawn.

Since the safety of Ovulen and Demulen in pregnancy has not been demonstrated, it is recommended that for any patient who has missed two consecutive periods pregnancy should be ruled out before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule the possibility of pregnancy should be considered at the time of the first missed period.

A small fraction of the hormonal agents in oral contraceptives has been identified in the milk of mothers receiving these drugs. The long-range effect to the nursing infant cannot be determined at this time.

Precautions—The pretreatment and periodic physical examinations should include special reference to the breasts and pelvic organs, including a Papanicolaou smear since estrogens have been known to produce tumors, some of them malignant, in five species of subprimate animals. Endocrine and possibly liver function tests may be affected by treatment with Ovulen or Demulen. Therefore, if such tests are abnormal in a patient taking Ovulen or Demulen, it is recommended that they be repeated after the drug has been withdrawn for two months. Under the influence of progestogen-estrogen preparations pre-existing uterine fibromyomas may increase in size. Because these agents may cause some degree of fluid retention, conditions which might be influenced by this factor, such as epilepsy, migraine, asthma, cardiac or renal dysfunction, require careful observation. In breakthrough bleeding, and in all cases of irregular bleeding per vaginam, nonfunctional causes should be borne in mind. In undiagnosed bleeding per vaginam adequate diagnostic measures are indicated. Patients with a history of psychic depression should be carefully observed and the drug discontinued if the depression recurs to a serious degree. Any possible

Demulen®

Each white tablet contains:
ethynodiol diacetate 1 mg./ethinyl estradiol 50 mcg.

influence of prolonged Ovulen or Demulen therapy on pituitary, or adrenal, hepatic or uterine function awaits further study. A decrease in glucose tolerance has been observed in a significant percentage of patients on oral contraceptives. The mechanism of this decrease is obscure. For this reason, diabetic patients should be carefully observed while receiving Ovulen or Demulen therapy. The age of the patient is not an absolute limiting factor, although treatment with Ovulen or Demulen may mask the onset of the climacteric. The pathologist should be advised of Ovulen or Demulen therapy when relevant specimens are submitted. Susceptible women may experience an increase in blood pressure following administration of contraceptive steroids.

Adverse reactions observed in patients receiving oral contraceptives—A statistically significant association has been demonstrated between use of oral contraceptives and the following adverse reactions: thrombophlebitis, pulmonary embolism and cerebral thrombosis.

Although available evidence is suggestive of an association, the relationship has been neither confirmed nor refuted for the following serious adverse reactions: neuro-ocular lesions, e.g., retinal thrombosis and optic neuritis.

The following adverse reactions are known to occur in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal disturbances (such as abdominal cramps and bloating), breakthrough bleeding, spotting, change in menstrual flow, amenorrhea during and after treatment, edema, chloasma or melasma, breast changes (tenderness, enlargement and secretion), change in weight (increase or decrease), changes in cervical erosion and cervical secretions, suppression of lactation when given immediately post partum, cholestatic jaundice, headache, nervousness, dizziness, fatigue, backache, hirsutism, scalp hair, erythema multiforme, erythema nodosum, hemorrhagic eruption and itching.

Although the following adverse reactions have been reported in users of oral contraceptives, an association has been neither confirmed nor refuted: anovulation post treatment, premenstrual syndrome, changes in libido, changes in appetite, cystitis-like syndrome, nervousness, dizziness, fatigue, backache, hirsutism, scalp hair, erythema multiforme, erythema nodosum, hemorrhagic eruption and itching.

The following laboratory results may be altered by the use of oral contraceptives: hepatic function: increased sulfobromophthalein retention and other tests; coagulation tests: increase in prothrombin, fibrinogen, VII, VIII, IX and X; thyroid function: increase in PBI and butanol extractable protein bound iodine, and decrease in T₃ uptake values; methylenetetrahydrofolate determination.

Rochester—A Community Becomes Aware and Responds

IT IS DIFFICULT to believe that as recently as seven years ago this moderate-sized southern Minnesota city, known for its progressive nature and professional sophistication, offered next to nothing in treatment or rehabilitative resources for alcoholic or drug-dependent persons. As a psychiatrist at a mental health center in 1966, I recall wondering where to go for help with an increasing number of alcoholic patients. No different from most physicians and psychiatrists, I had received little education regarding the management of these patients, and I found community resources almost nonexistent. This was early in the mushrooming public awareness of "drug abuse" and alcoholism in their many forms and disguises. Our community was caught unaware and unprepared, as were most. It is with a sense of pride, however, that we can now describe a network of services—certainly not ideal but a rather impressive and continuing response by community leaders who rapidly became aware of the problem.

Spearheading a lonely battle for some time was the Alcoholism Information Center (AIC), originating in 1964 under private sponsorship and becoming a permanent arm of the Zumbro Valley Mental Health Center (ZVMHC) in 1966. Working closely with an active local Alcoholics Anonymous program, the AIC, as the only available community agency, attempted to provide services of diagnosis, counseling, referral, consultation, and education. As a result of this leadership as well as the growing concern of a handful of medical and mental health professionals, there developed a skeletal network for alcoholic people. This included a short-term inpatient program at Rochester State Hospital (RSH), psychiatric evaluation and group-oriented therapy through ZVMHC, a community lecture series open to the public (which continues at this time), and a detoxifica-

tion service plus medical consultation through one interested internist and the Olmsted Community Hospital.

The similarities among drug abuse, drug dependence, and alcoholism were brought into dramatic focus in 1970 by nationally known leaders who keynoted a YMCA-sponsored conference on drug abuse. Organized as a direct result of this conference was RADAR (Rochester Area Drug Abuse Response). Its board of directors, made up of students and adults in equal numbers, has gradually led a once loosely knit and vague program to the point of community credibility and permanent funding by providing an Awareness House drop-in center, a "Sunrise" hotline, and increasing educational services.

A 24-bed Alcoholism Treatment Unit, a joint project of the Mayo Clinic and Rochester Methodist Hospital, opened in March 1972. This unit provides comprehensive evaluation and treatment of alcoholic problems and also offers, under the direction of the Department of Psychiatry, training in alcoholism problems (now required for all psychiatric residents in the Mayo Graduate School of Medicine). An outgrowth of this program is a 4-hour educational block on alcoholism to be provided this spring for freshman students at Mayo Medical School.

Currently in weekly session at Mayo for the winter quarter (three months) is a seminar series on alcoholism and drug dependence sponsored jointly by the Committee on Alcoholism of the Zumbro Valley Medical Society and the Mayo Clinic Department of Psychiatry and Department of Environmental Medicine. The series involves Mayo consultants and residents as well as community experts.

During the past year, a Chemical Dependency

"A VEHICLE OF LIFE"

Tennis is so much more than learning a proper forehand, volley, etc. Gamesmanship was invented for the game of tennis. Many times you have seen a mechanically superior player beaten by the mentally mature player — in every class of player — in any age bracket.

National Tennis Schools will give a student, regardless of playing ability, a philosophy and the sensitivity to analyze the opponent versus himself; this will place the student dimensions above his peer group.

This is the tennis product that we are most excited about. This philosophy becomes a second nature and can never be taken from a student . . . whether used for tennis competitively or if not used for years. We have given our student something that no one can take away — and this new talent will become part of his life style.

National Tennis Schools, Inc. brings you ten years of experience operating co-educational tennis camps.

Location meeting our requirements at Shattuck School in Faribault, Minnesota. 250 acre campus, lakes for water sports, 18 tennis courts, 3 football fields, 2 soccer fields, 3 baseball diamonds, and a 9 hole golf course.

Facilities include semi-private modern rooms.

BOYS AND GIRLS 9-16 AND ADULT PROGRAM.

For information write National Tennis Schools, 6800 France Ave. So. Minneapolis, MN 55435 or call (612) 920-5353

A TENNIS PROGRAM UNDER THE MOST IDEAL CONDITIONS

**national
tennis
schools** inc.

6800 FRANCE AVENUE SOUTH • MINNEAPOLIS, MINNESOTA 55435 • AREA CODE 612-920-5353

Training Course, offered through the University of Minnesota extension service but staffed with local faculty, and partially funded by local sources, has begun the task of educating a growing number of people desiring work in this field.

Added to the above are an active, conscientiously directed detoxification center (at Rochester State Hospital but under the ZVMHC umbrella), the Rochester Guest House residential program for priests, work nearing completion to

incorporate a Halfway House, and a growing municipal court program for alcohol-related crimes. Much has been accomplished in a short time—a tribute to an active and concerned community which responded after becoming aware.

Certainly we, as physicians, can and should share with other responsible citizens the leadership needed to work toward solution of the ongoing drug-dependence epidemic.

Mayo Clinic and Mayo Foundation
Rochester, Minnesota

Juvenile Nasopharyngeal Angiofibroma

MOST EPISTAXIS results from nasal dryness or the rupture of engorged degenerative vessels. Only occasionally does epistaxis prove to be the presenting symptom of a nasal tumor. Nevertheless angiofibroma illustrates just such a tumor. Adolescent boys rarely have epistaxis except in connection with trauma and any nosebleed in this age should be suspect. Duvall et al.* have presented an excellent review of this tumor.

Angiofibromas can often be seen on anterior nasal inspection as a dark red mass. A lateral skull Xray will show a mass in the nasopharynx. Teenage boys should have small degenerating adenoid masses and their nasopharynx should be clear on Xray. Biopsy of the tumor outside the surgical

theater is hazardous because of the likelihood of massive hemorrhage.

Surgery is the most valuable form of therapy as the tumor tends to be radioresistant. Pre-operative estrogen therapy seems to decrease vascularity and facilitate dissection.

Angiography is the most recent advance in the care of angiofibromas. The tumor will stain and its size and location can be determined. Expansion of angiofibromas can occur into the orbit, the infratemporal fossa and even the middle cranial fossa. Although histologically benign the angiofibroma can be a medical challenge in its control.

Tracheobronchial Lavage

DOCTOR BURKE-STRICKLAND'S* paper on "Tracheobronchial Lavage in Small Infants" published in this issue of MINNESOTA MEDICINE deserves comment. It further demonstrates the usefulness of active and effective intervention, once thought meddlesome, in the care of the sick infant.

With the recent interest in the intensive care of the sick infant, rapid strides have been made in nursing techniques and in special procedures to aid in establishing normal pulmonary function. This technique has been proven to be beneficial to Doctor Burke-Strickland's patients. Its greatest

use would probably be in those neonates with meconium aspiration syndrome.

As with other sophisticated techniques that have developed in infant intensive care, tracheobronchial lavage should be done in an infant intensive care unit staffed by a full complement of fully trained nurses and the procedure done by a highly-skilled physician. Doctor Burke-Strickland and her unit at Hennepin General Hospital clearly fulfill those criteria.

Robert Feldt, M.D.

Retroperitoneal and Mesenteric Xanthogranuloma

THE RARE AND unusual lesion of xanthogranuloma* wherever it is located, still is seeking a place of rest in classification and nomenclature. The elements present could be part of a reactive process as in inflammation and at the same time resemble histiocytic lesions and tumors of the histiocytoma group.

It is interesting to speculate that the lipid leaked from a capillary from trauma, obstruction or microscopic defect, brings about a similar type of response wherever it occurs. Similar microscopic pseudogranulomas have been seen in bone marrow sections and appear to be reactive rather than tumor. The continued expanding response to altered tissue or "extra-vascular-vascular" fluids

not removed by lymphatics, could conceivably cause such a tumor. Electron microscopic studies have shown that a vascular defect can exist in these lesions.

The confused mingling of florid reactive processes involving fibroblasts, histiocytes, and other multipotential cells has left us with a collection of lesions neither purely inflammatory nor purely malignant tumors. Xanthogranuloma at present rests in that middle ground with other lesions, such as pseudosarcomatous fasciitis or various histiocytomas.

Packed Red Blood Cells

TRANSFUSION THERAPY, whether to replace acute surgical blood loss or to raise the hemoglobin of an anemic patient not responsive to other forms of treatment, must be tailored to the patient's needs. Dr. McCullough in his paper* points out that except for hypovolemia with acute blood loss, Red Blood Cells (human)—packed cells, is the component of choice. The patient receives the benefit of the entire mass of hemoglobin for oxygen transport with only one third as much anticoagulant and donor plasma proteins as in a unit of whole blood. There are fewer adverse reactions following transfusion with packed cells and possibly less transfusion associated hepatitis. Because of these advantages of removing some of the plasma, many predict that in the future all transfusions containing red cells will be frozen blood that has been thawed and resuspended in physiologic saline.

Until recently the only disadvantage of packed

cells has been difficulty in administration. This no longer is a problem if one uses the technique suggested by McCullough.

Though not specifically related to the therapy of an individual patient needing a transfusion, the use of packed cells rather than whole blood is important in the overall management of the blood resource. The blood bank must depend on the small segment of the population (less than three percent of those eligible) willing to give their blood. From this we must meet the demands for fresh frozen plasma, antihemophilic globulin, platelets, plasma to be converted to plasma protein fraction and gamma globulin etc. Thus everytime a patient unnecessarily gets whole blood he is at greater risk and the blood resource is depleted of components that could save another patient's life.

Congenital Abnormalities of the Coronary Arteries

THE INTERESTING case report of Kiser and Schultz* raises several questions. The title is "Congenital Coronary Arterial Venous Fistula" whereas the case report describes what appeared to be anomalous origin of the right coronary artery from the pulmonary artery. The discussion and references do not recognize anomalous origin of coronary arteries as a different abnormality with different pathophysiological and therapeutic implications.

Primary anomalies of coronary arteries may be divided into two major groups depending upon whether the entire coronary system arises from the aorta or at least part of the coronary circulation arises anomalously from the pulmonary artery.¹ Coronary artery fistula usually refers to a congenital abnormality in which the coronary arteries originate normally from the aorta but an abnormal fistula drains preferentially to the right ventricle, an atrium, the coronary sinus, the pulmonary artery or a bronchial vessel instead of to the coronary vein via a normal coronary and myocardial distribution. Anomalous origin of a coronary artery indicates a normal distal coronary distribution but one of the coronary arteries originates from the pulmonary artery instead of from the aorta. In this circumstance a sizable left to right shunt to the pulmonary artery may develop via enlarged but normally distributed coronary collaterals from one coronary system to the other.² With the exception of the peculiar thin walled structure with questionable connections to the aorta and pulmonary artery, the case described by Kiser and Schultz would seem to best fit the latter diagnosis.

The pathophysiology of different primary anomalies of the coronary arteries varies greatly. With coronary arterio-venous fistulae the dominant physiologic abnormality is the shunt which may cause an increased pulse pressure, heart failure and a continuous precordial murmur. Complications include bacterial endocarditis and aneurisms which may rupture causing acute hemoperi-

cardium. Myocardial ischemia can occur but is rare. Anomalous origin of the left coronary artery from the pulmonary artery is very serious because as the pulmonary artery pressure drops to normal after birth, coronary flow to the left ventricle may be severely compromised and ischemic symptoms develop, often first noted as a feeding problem in infancy. Anomalous origin of the right coronary artery from the pulmonary artery on the other hand is usually a benign condition without serious clinical consequences.³ The condition may become manifest as an adult because of a continuous murmur confused with a patent ductus arteriosus but evidence of myocardial ischemia is rare. When large collaterals permit a large left to right shunt or a continuous murmur to develop, the diagnosis of anomalous origin of a coronary artery is usually obvious by aortography if the contrast injection is made into the aortic root. The distal coronary distribution is normal but the coronary arteries are very large and the coronary artery that arises anomalously from the pulmonary artery fills late with retrograde flow.

Anomalous origin of the left coronary artery from the pulmonary artery may require reconstructive surgery but simple ligation of an anomalous right coronary artery at its origin from the pulmonary artery may be all that is necessary to correct both the shunt and any ischemic symptoms. We have studied a patient with anomalous origin of a right coronary artery in which an attempt was made to transplant the right coronary artery from the pulmonary artery to the aorta. Postoperative angiograms demonstrated that the transplanted artery had closed proximally, presumably from thrombosis caused by the high distal coronary back pressure related to large collaterals. The use of reversed saphenous vein by-pass is also a logical anatomical method of surgical correction but might be expected to result in thrombosis for the same physiological reasons. A follow-up selective angiogram of the vein graft in the case described by Kiser and Schultz, therefore, would be both inter-

*Kiser Joseph C and Schultz Robert: Congenital coronary arterial venous fistula, repair. *Minnesota Med* 55:988, 1972.

esting and instructive, especially since many of

the collateral channels were apparently ligated.

Circulating Blood Flukes

SCHISTOSOMIASIS is a chronic and debilitating disease, as demonstrated in the remarkable series of cases by Haedicke in the December issue of MINNESOTA MEDICINE.* Transmitted to humans through contaminated water the fluke has a highly consistent and complex life cycle that is a biological wonder.

According to the World Health Organization¹ schistosomiasis is endemic in many areas of the world. It is estimated that there exist 200,000,000 infected persons in the less technically advanced countries. Travelers can become infected through drinking water from a questionable source or by swimming in such waters with entrance of the parasite through the skin. The disease can usually only be proved through the demonstration of the ova in either the feces or urine or by mucosal biopsy of the rectum.

One of the most spectacular and little known stories of schistosomiasis relates to the planned invasion of Taiwan (Formosa) by the Chinese Nationalists in 1950, as recorded by Frank Kierman, Jr.[†] The defenses of Taiwan were vulnerable to a waterborne attack from the Chinese Mainland. Transportation of trained Nationalist troops would be made in wooden junks, and then for a short distance at the termination of the journey the men would swim ashore. In preparation for this invasion the troops were given intensive swimming lessons in canals of southern Chekiang and northern Fukien. Unfortunately the waters were inhabited by *Schistosoma japonicum*, and 30,000 to 40,000 men became infected and disabled. Medical care was inadequate; time for the invasion was at hand, and the military project failed because of this blood fluke.

Cover Painting

"Water Lilies"

Dr. Herbert W. Johnson began painting in 1967, and the cover is the result of early summer viewing of the swamp areas in the neighborhood of Mendota Heights. These areas no longer exist today.

This particular painting won first prize in the Dakota County Art Fair, a few years back.

Dr. Johnson is an Associate Professor in Internal Medicine at the University of Minnesota and in addition, practices in St. Paul. He spends most of his spare time painting and sailboating.

Letter to the Editor

As a result of the efforts of many pioneer vascular surgeons in the past, prosthetic cardiac valve replacement can now be done with a relatively low mortality rate. Their efforts should humble even the most outspoken present day surgeon. Even with these advancements it does not require much time or realism to discover the true palliative nature of cardiac valve replacement.

Nothing is more discouraging than to see a patient successfully undergo a serious procedure, to recover and enjoy life less plagued by symptoms, only to suffer from the complications of thromboembolism or prosthetic valve endocarditis. Fortunately the majority of these complications are reversible; however, in spite of improvements in valve design, they continue to take their untimely toll. Recent reminders have emphasized the need to alert physicians and dentists about therapeutic levels of anticoagulation. It behooves everyone involved with these patients to be aware of other pharmaceutical products which will interfere with prothrombin levels. Until the ideal prosthetic replacement is available, maximum sustained therapeutic improvement can only be maintained by a continued careful medical and dental awareness.

The problems of prosthetic valve infection can be minimized through the use of prophylactic antibiotics during dental care. The dental profession must be alert to the disastrous consequences of this complication.

With diligence on our part and an awareness by the oral surgeon we can help sustain that palliative improvement which valve replacement can provide.

Decubitus Ulcers Yield to

Travase® Ointment

brand of **Sutilains**

Before treatment, necrotic matter coated the inner surfaces of this decubitus ulcer.

After six days of TRAVASE therapy, debridement is nearly complete and granulation evident.

Active Therapy—Observe Its Effects in 48 hours
If the recommended nursing technique is followed without deviation, this procedure can produce visible improvement within 48 hours of treatment. If no dissolution of slough occurs by then, further application is unlikely to be rewarding. Watch for break in procedure, usually due to use of drying or antiseptic agents which impair the effectiveness of the enzyme in TRAVASE).

Travase® Ointment brand of Sutilains

APPLICATION TECHNIQUE: TRAVASE Ointment is indicated as an adjunct to established methods of wound care for biochemical debridement. It dissolves and facilitates the removal of necrotic tissues and purulent exudates.

TRAVASE enzymes are selective. Virtually inactive on viable tissue.

When this recommended nursing technique is followed without deviation, this procedure can generate visible improvement within 48 hours . . .

(Ulcer being irrigated)
Thoroughly cleanse and irrigate the wound area using only sterile water or sodium chloride solution. Be sure to cleanse the wound of any antiseptics or heavy-metal antibacterial agents which may interfere with the enzyme activity.

Thoroughly soak the wound area. Where practical, tubbing or showering is suitable. Or wet soaks with gauze pads may be used. Remember to avoid chemical cleansing agents which may interfere with the therapy.

With a sterile cotton swab or finger cot, apply a very thin layer of TRAVASE Ointment. The ointment spreads easily and only a small amount is needed (a small dab of ointment will cover an area as big as the back of a hand).

Be sure, though, to rub the ointment well into every crack or crevice of the wound and overlap the surrounding skin one-fourth to one-half inch beyond the area to be debrided—to be sure of complete coverage.

Apply loose, wet dressings, thoroughly soaked in sodium chloride solution or sterile water to the area to be debrided only.

Cover the moist dressings with an occlusive wrap (Saran wrap, Telfa Pads, or other plastic wrappings) to keep wound site moist. Do not extend occlusive wrap over 1/2 inch beyond area to be debrided.

When changing dressing, gently wipe away the dissolved material. Repeat the complete dressing procedure, including application of TRAVASE Ointment, four times daily.

The ulcer shown in these photos is simulated on a model in order to demonstrate the correct TRAVASE application technique.

DESCRIPTION: TRAVASE® (brand of sutilains) Ointment is a sterile preparation of proteolytic enzymes, elaborated by *Bacillus subtilis* hydrophobic ointment base consisting of 95% white petrolatum and polyethylene. One gram of ointment contains approximately 82,000 units* of proteolytic activity.

ACTION: TRAVASE Ointment selectively digests necrotic soft tissue proteolytic action. It dissolves and facilitates the removal of necrotic tissues and purulent exudates that otherwise impair formation of granulation tissue and delay wound healing (4).

At body temperatures these proteolytic enzymes have optimal activity at the pH range from 6.0 to 6.8.

INDICATIONS: For wound debridement (1,2)—TRAVASE Ointment is indicated as an adjunct to established methods of wound care in biochemical debridement of the following lesions:

- Second and third degree burns,
- Decubitus ulcers,
- Incisional, traumatic, and pyogenic wounds,
- Ulcers secondary to peripheral vascular disease.

CONTRAINDICATIONS: Application of TRAVASE (brand of sutilains) Ointment is contraindicated in the following conditions:

- Wounds communicating with major body cavities,
- Wounds containing exposed major nerves or nervous tissue,
- Fungating neoplastic ulcers,
- Wounds in women of child-bearing potential—because of lack of laboratory evidence of effects of TRAVASE upon the developing fetus.

Do not permit TRAVASE Ointment to come into contact with the eyes. In treatment of burns or lesions about the head or neck, the ointment inadvertently come into contact with the eyes, the eyes should be immediately rinsed with copious amounts of water, preferably sterile.

PRECAUTIONS: A moist environment is essential to optimal enzyme activity. Enzyme activity may also be impaired by certain agents: several detergents and antiseptics (benzalkonium chloride, hexachlorophene, iodine, and nitrofurazone) may render the substrate indifferently to the action of the enzyme (3). Compounds such as containing metallic ions interfere directly with enzyme activity to a slight degree, whereas neomycin, sulfamylon-streptomycin, and do not affect enzyme activity. In cases where adjunctive topical has been used and no dissolution of slough occurs after treatment with TRAVASE Ointment for 24 to 48 hours, further application, because of interference by the adjunctive agents, is unlikely to be rewarding.

In cases where there is existent or threatening invasive infection, appropriate systemic antibiotic therapy should be instituted concurrently.

Although there have been no reports of systemic allergic reactions in humans, studies have shown that there may be an antibody response to humans to absorbed enzyme material.

ADVERSE REACTIONS: Adverse reactions consist of mild, transient paresthesias, bleeding and transient dermatitis. Pain usually can be controlled by administration of mild analgesics. Side effects severe enough to warrant discontinuation of therapy occasionally have been reported.

If bleeding or dermatitis occurs as a result of the application of (brand of sutilains) Ointment, therapy should be discontinued. No toxicity has been observed as a result of the topical application of TRAVASE Ointment.

Dosage and Administration

STRICT ADHERENCE TO THE FOLLOWING IS REQUIRED FOR RESULTS OF TREATMENT

1. Thoroughly Cleanse and Irrigate Wound Area with sodium chloride solution. Wound **MUST** be cleansed of antiseptics, heavy-metal antibacterials which may denature enzyme substrate characteristics (e.g., Hexachlorophene, Silver, Benzalkonium Chloride, Nitrofurazone, etc.).
2. Thoroughly moisten wound area either through tubbing or wet soaks (e.g., sodium chloride or water solutions).
3. Apply TRAVASE Ointment in a thin layer assuring intimate contact with necrotic tissue and complete wound coverage extending 1/4 to 1/2 inch beyond the area to be debrided.
4. Apply loose wet dressings.
5. Repeat entire procedure 3 to 4 times per day for best results.

How Supplied

3P3002 TRAVASE Ointment is supplied sterile in one-half ounce (14.2 g.) containing 82,000 casein units of sutilains per gram in a hydrophobic ointment base.

The ointment must be stored under refrigeration at 2° to 10° C (35° to 50° F).

X-ray Conference

Calcifications in the Bladder Wall

A 35-YEAR-OLD WOMAN was hospitalized with a history of chills, fever and back pain for three to four days. The physical examination was essentially negative. The white count was 8,700/cmm with 74% neutrophils. Urinalysis showed 2+ albumin and numerous white blood cells.

The KUB film shows linear calcifications in the region of the bladder (Figure, arrows).

At this point the radiologist inquired about the nationality of the patient.

Figure

Diagnosis: Urinary schistosomiasis (bilharziasis).

The patient was a recent immigrant from Egypt. The disease, caused by *Schistosoma haematobium*, is endemic in Egypt and throughout Africa. It is also found in other areas of the Middle and Near East, the Malagasy Republic, Portugal and a small area near Bombay, India. The adult flukes live in the vesical and pelvic venous plexuses. Ova are deposited in the submucosal venules of the urinary bladder and subsequently escape into the perivascular tissue causing progressive cystitis with ascending secondary infection of ureters and kidneys. Polyps, carcinoma and contraction of the bladder, ureteral stricture, urinary stones, hydronephrosis, urethral stricture and involvement of the prostate and seminal vesicles are common sequelae. Calcification may be demonstrated in these areas roentgenographically. In the bladder it is linear (Figure) or "cloudlike" in appearance.

The current symptoms of this patient were attributed to acute pyelonephritis due to *E. coli* and responded promptly to antibiotic therapy. Excretory urography disclosed normal kidneys and ureters and confirmed the intramural location of the bladder calcification. Although *S. haematobium* ova were not found in the urine, the radiographic finding of such calcification in a person from Egypt was virtually pathognomonic of bilharziasis.

Moore's Syndrome

A small number of children and young adults who were subject to irregular recurrent paroxysms of unexplained abdominal pain were found to have abnormal electroencephalograms. Klingman and associates studied 12 such cases; Moore, whose eponym is used, described the syndrome, which he termed a form of symptomatic epilepsy, and reported an additional case.

The attacks usually occurred over a period of years, beginning with sudden cramplike pain involving the entire abdomen, accompanied by nausea and vomiting. The severity often caused prostration. Convulsive manifestations were evident during some period in nine of the patients studied by Klingman. Electroencephalographic findings were suggestive of cerebral dysrhythmia, mostly of the psychomotor equivalent pattern. In Moore's patient, abnormally slow waves were observed, particularly over both frontal lobes. Considerable experimental and clinical evidence has indicated injury to the cerebral cortex, especially of the frontal lobes. This localization may involve the premotor area as well as Brodmann's areas three and five, and perhaps six (Moore). Anticonvulsant therapy brought about a cessation of attacks and restored the alpha activity to the EEG tracings.

Pelvic Mass in a 65-Year-Old Female

CURTIS J. LUND, M.D.*, DAVID W. GAUGER, M.D.† AND JOHN A. REICHERT, M.D.‡

A 65-YEAR-OLD WHITE female, para 3-0-1-3, whose last menstrual period was at age 38, was seen in the Gynecology Clinic at Hennepin County General Hospital because of lower abdominal pain for three weeks, loss of appetite, and constipation. Abdominal and pelvic examination revealed a cystic mass filling the pelvis and extending to the umbilicus. A diagnosis of ovarian tumor was made.

Two weeks later she was admitted to the hospital and had new complaints of abdominal distention, nausea and vomiting, and weight loss. She also complained of intermittent watery, brownish vaginal discharge for two weeks. The patient stated that since regular menses had stopped, she had vaginal bleeding of three to five days duration, occurring about every three months. Past and family history were otherwise non-contributory.

Physical examination on admission revealed an obese, lethargic, white woman in acute distress. The pulse rate was 90 and the blood pressure 160/75. Her skin showed loss of turgor with "tenting." No lymph nodes were palpated. Mucous membranes of the mouth and throat were dry. The chest was clear. The liver and spleen were not palpable. A mass, extending to just above the umbilicus was felt and ascites was also detected.

Pelvic examination showed atrophic vulvar and vaginal tissue with no vaginal lesions. The cervix was small and grossly free of tumor. The mass was movable and very tender. There was 2+ pitting edema of both ankles.

Initial laboratory studies revealed a hemoglobin of 11.7 gms., hematocrit 35.9, 81% neutrophils, and a white count of 11,600. Urinalysis revealed a specific gravity of 1.016, pH 5.2, and 1+ albumin. The arterial pH was 7.45, pCO₂ 24 mm, and

pO₂ 98 mm. The sodium was 130 mEq, potassium 3.7 mEq, chloride 107 mEq, and CO₂ was 11 mEq. The blood sugar was 222 mg and serum acetone was negative. The serum creatinine was 3.4 mg and the BUN 55 mg. The BSP was 13% at 45 minutes. Urine cultures were sterile. Chest Xray on admission was normal.

The patient was treated on admission with 5% dextrose in 1/2-normal saline and 20 mEq. of KCl/1000 ccs. of fluid. The patient received 2400 cc. of fluid over the first 24 hours of her admission and had only 600 cc. of urine output. Her urine output subsequently dropped to 10 cc. per hour. Sodium bicarbonate and lasix were added to her therapy, without response.

On the second hospital day, the sodium was 127 mEq, potassium 4.6 mEq, chloride 96 mEq, CO₂ 12 mEq, hemoglobin 11.4 gms and hematocrit 33.9%. The arterial pH was 7.41, pCO₂ 17 mm, pO₂ 88 mm. The urine specific gravity was 1.010 and the urine output gradually decreased to zero. The central venous pressure (CVP) was measured at zero. Intravenous mannitol and sodium-free plasma infusions were initiated. The following morning the patient had generalized pulmonary rales and audible gurgling with respirations. She received 80 mg. of lasix and 0.5 mg. of digoxin intravenously. The urine output increased to 20 cc. per hour and her CVP at this time measured 15. She began to bleed from venipuncture sites. A prothrombin time was 14.3 seconds with a control of 12 seconds and the PTT was 40.9 seconds with a control of 34.1 seconds. The fibrinogen was 0.21 gm., thrombin time 12.5, and fibrin split products had a titer of 1:64. Her hemoglobin was now 8 gms, hematocrit 25.2 and normal red cell indices. The platelet count was 142,000.

Abdominal distention increased and a paracentesis was done on the fourth hospital day; 75 cc. of bloody fluid was removed. The hematocrit on this fluid was 14 and a Gram stain revealed red and white blood cells but no bacteria. The

*Professor of Obstetrics-Gynecology, University of Minnesota, Minneapolis, Minnesota.

†Resident in Pathology, Hennepin County General Hospital, University of Minnesota, Minneapolis, Minnesota.

‡Department of Obstetrics-Gynecology, St. Louis Park Medical Center, St. Louis Park, Minnesota.

patient continued to be oliguric despite repeated courses of lasix and mannitol. She developed a fever of 101°F and 100,000 colonies cc of *E. coli* were cultured from her urine. An exploratory laparotomy on the fifth hospital day revealed a pelvic mass measuring 24 x 16 x 16 cm. The mass was not removed. The space of Retzius and flanks were drained and the wound was closed. A ureteral catheter was inserted on the left side but the right ureteral orifice was not found. The patient awoke after surgery and remained anuric. The patient became hypotensive 16 hours after surgery and died on the morning of the sixth hospital day.

Clinical Discussion

Curtis Lund, M.D.:

The patient is a 65-year-old multiparous female who had a premature menopause at the age of 38 which was about 27 years before this hospitalization. The patient had somewhat regular uterine bleeding every two to three months until shortly before her admission when she began having watery brown vaginal discharge. The history of intermittent vaginal bleeding for several years is difficult to explain on an endocrinological basis but is significant in this patient's history.

The second significant feature in this patient's history is the lower abdominal pain which had been present for approximately three weeks. She had also noted anorexia, abdominal pain, constipation, abdominal distention, nausea, vomiting, and weight loss over a period of a few weeks although the patient was confused, so perhaps her history is not reliable. Despite her appearance of dehydration, the patient was described as having lower extremity edema and ascites. These findings, in combination with the finding of a large pelvic mass, would suggest that the pelvic mass had begun to encroach upon the venous and lymphatic return of the lower extremities.

On abdominal and pelvic examination the mass within the pelvis and abdomen was firm and extending above the umbilicus. Also, the mass was described as being very tender. Abrupt changes within a malignant mass such as hemorrhage into infarcted, necrotic areas or infection can cause pain and tenderness. Interestingly, the mucous membrane of the vagina and the cervix was described as being atrophic. We have a patient who has vaginal bleeding for approximately 25 years and now is described as having an

atrophic mucosa. An actively functioning granulosa thecal cell tumor would not be likely in the presence of atrophic vaginal and cervical mucosa. There is no information regarding whether the uterus had been sounded at the time of the initial pelvic examination. It would be advisable to sound the uterus under these circumstances and to examine the tissue which might be removed from the uterus at the time. The sounding of the uterus would also be helpful in determining the size of the uterus.

When there is ascites present in the absence of hepatic, renal or cardiac disease, a pelvic neoplasm of ovarian origin and occasionally of gastrointestinal origin must be considered. Tuberculosis must also be considered. Rarely one finds ascites with an ovarian fibroma, the so-called Meig's syndrome. Occasionally large uterine myomata in the absence of other abnormalities cause ascites.

The hematocrit of 35 in the presence of dehydration represents hemoconcentration. The serum potassium and sodium are low and in the presence of a pH of 7.45, which is tending towards alkalosis, would suggest vomiting of electrolytes and hydrochloric acid. However, a chloride of 107 is not consistent with this hypothesis.

After admission the patient was hydrated in an attempt to correct the electrolyte abnormalities. During the first day of the patient's admission she had approximately 2400 cc. of fluids and had only a 600 cc. urine output. The urinary output continued to diminish despite the use of diuretics. The specific gravity of 1.016 in the presence of dehydration suggests an inability of the kidneys to concentrate the urine. The following day there was essentially no urine output. At the same time the CVP was recorded as zero. I am not able to explain the zero reading. At this time the patient received mannitol and plasma in an attempt to increase urinary output. During the therapy she developed acute pulmonary edema. The therapy did increase urinary output somewhat and also increased the CVP. With the hydration therapy there was found to be a drop in the hematocrit.

At this time there was also noted to be some bleeding from the venipuncture sites. Now I cannot qualify as a hematologist, but I think the important laboratory results at this time are the essentially normal prothrombin time, the distinctly elevated PTT, the satisfactory fibrinogen level and the fibrin split product titre of 1:64. The fibrin split products could be explained by

the presence of a tumor. Certainly, we know that in some malignancies there is a state of hypercoagulability and with fibrin lysis, one would expect some degree of fibrin split products. I do not believe that these values indicate disseminated intravascular coagulation.

The patient developed increased abdominal distention and a paracentesis revealed a fluid of the same color as venous blood. Its hematocrit was 14 when the patient's hematocrit was 25, indicating a significant amount of blood in the paracentesis sample. In the presence of a large pelvic tumor mass and ascites, the paracentesis needle can be inserted into the tumor and fluid can be withdrawn from the tumor itself. I think there is a distinct possibility that the trochar went into a loculated cavity of the neoplasm. Blood can be present in ascitic fluid, but in the presence of significant ascites, a hematocrit of 14 represents a considerable amount of blood within the peritoneal cavity. It is assumed that the trochar was most likely within a loculated cyst of the neoplasm. This fluid had both red and white blood cells so it represented a relatively recent hemorrhage that may have partly caused the decreased hematocrit.

The patient remained essentially anuric. Is this pre-renal or renal failure; or a post-renal obstruction with renal failure? The clinical course doesn't answer this and the reason will have to remain obscure. I suspect a considerable degree of post renal obstruction due to a pelvic tumor encroaching upon the base of the bladder or the ureters.

A laparotomy was done. I don't know what the pre-operative diagnosis was but this large tumor, reaching above the umbilicus, could hardly come from anything other than the ovaries or uterus. A tubal disease of this magnitude is almost unheard of. As far as the uterus is concerned, I think we have to keep in mind this long history of uterine bleeding. This bleeding history would be consistent with a myomatous uterus, if some of the myomas were in the submucous position and periodically bled into the endometrial cavity. Something could have happened to change these, such as the development of a sarcoma within the uterus. This sequence of events could explain all the gynecological features.

A tumor of this size could be of ovarian origin. Huge ovarian tumors are usually cystic and often are mucinous cystadenomas or mucinous cystadenocarcinomas. A mucinous cystadenocarcino-

ma is, therefore, a likely preoperative diagnosis. This could have been one of the so-called solid ovarian malignancies which can grow to a considerable size. Frequently, however, these neoplasms spread to the omentum, forming an omental cake, and when you examine the patient, you feel a mass up to the umbilicus and above. An ovarian neoplasm would not explain the uterine bleeding, except in the case where an ovarian metastasizes to the endometrial cavity and then causes uterine bleeding. This would not explain, however, the many years of intermittent bleeding this patient had.

There are a number of extra-genital tumors that have to be considered. One consideration is a solitary pelvic kidney but the pelvic kidney is not a tumor of this size. For this to represent a pelvic kidney, something pretty disastrous would have had to happen. Possibly a hydronephrosis or something of that nature could have caused such a large mass.

There are primary peritoneal tumors which I will not discuss at this time. Also to be considered are retroperitoneal tumors. The largest one of these that I have seen was a liposarcoma. Other neoplasms, particularly the neural tumors, can occur in the retroperitoneal space. However, none of these would explain the findings in this case, except for the pelvic mass.

A laparotomy was done and after exploration the incision was closed and drained without the removal of the mass. Following surgery, the patient became anuric and died. Why was the mass left in-site and only biopsied? Either this structure, whatever it was, shouldn't be removed and therefore was not, or the structure couldn't be removed. Now, what shouldn't be removed? It could have been a solitary kidney, and therefore, could not be removed. If one was dealing with an uterine malignancy that could not be removed in toto, then an attempt might be deferred and the patient treated with radiation therapy. If it was an ovarian tumor, certainly one would attempt to remove as much as he could. If this was an ovarian cyst, one should be able to remove the major part of the tumor. Of the tumors that could not be removed, one would be an extensive adenocarcinoma of the ovary which involved the lateral pelvic walls and the ureters. Similarly, an extensive uterine sarcoma which had spread to the pelvic walls is very difficult, if not impossible,

to remove because of the extensive bleeding that may be encountered. Patients have died from surgical attempts to remove a pelvic sarcoma.

My first diagnosis is uterine sarcoma. The second is metastatic ovarian carcinoma; and the third primary ovarian carcinoma. I can't dismiss the possibility of a pelvic kidney. The placement of drains in the space of Retzius is very suspicious for a renal problem.

Clinical diagnosis: uterine sarcoma.

David W. Gauger, M.D.:

Dr. Lund's conclusion is correct. The tumor is a uterine sarcoma. The immediate cause of the patient's death was an acute pulmonary embolus

to the right lower lung (Figure 1). The lungs had a combined weight of 1040 grams.

There was a pelvic mass that measured 24 x 2 x 18 cm. 3700 gms. The mass arose cephalad to the cervix in the region of the uterus. There were areas of firm neoplastic light yellow to brown tissue that was alternating with cystic areas of necrosis and hemorrhage (Figure 2). The tumor compressed the gastro-intestinal organs. The neoplasm was composed of round and fusiform cells and there were scattered cells that had cross striations characteristic of skeletal muscle (Figure 3). This malignancy was interpreted as being poorly differentiated, mixed mesodermal sarcoma.

Fig. 1—Pulmonary embolus involving right inferior lung.

Fig. 2—Mixed mesodermal sarcoma of uterus—arrow pointing to cervix.

The neoplasm had extended widely involving the serosa of the sigmoid colon as well as the serosa of the bladder. In addition, the malignancy had spread to involve the distal portion of the right ureter, compressing it and causing a right hydronephrosis. The neoplasm, however, had not involved the mucosa or the lumen of the right ureter. The left ureter was normal. There was no omental cake and there were no metastases to distant organs.

The kidneys were approximately symmetrical and had a combined weight of 420 grams. On gross examination, they were slightly softer than normal and had a more yellow appearance. The cortex was 4-6 mm thick and there was a distinct corticomedullary junction. On microscopic examination, the kidneys were interpreted as representing an arteriolar nephrosclerosis, characterized by sclerosis of the renal arteries with narrowing of their lumina as well as hyalinization and sclerosis of scattered glomeruli. There were areas of fibrosis and chronic inflammatory cell infiltration within the cortex. Some glomeruli had occasional neutrophils present. This was interpreted as being due to an early ascending renal infection.

Pathological diagnosis:

1. Acute pulmonary embolus, right lower lung.
2. Poorly differentiated mixed mesodermal sarcoma, uterus. (A) Extensive local infiltration.
 - (1) Infiltration of the serosa of the sigmoid colon and bladder.
 - (2) Extension to the distal right ureter with right hydronephrosis.
3. Arteriolar nephrosclerosis of both kidneys.

John A. Reichert, M.D.:

The diagnosis and management of mixed mesodermal tumors of the uterus has represented a gynecological enigma for many years, since they are rare but highly malignant.

Uterine sarcomas comprise less than 1% of all uterine neoplasms and only 15 to 20% of all uterine sarcomas are mixed mesodermal sarcomas. The tumor occurs in all races and the patients range from nulliparity to multiparity. The mean age is about 60 years and most are post-menopausal. From 10 to 25% of patients with uterine sarcomas have a history of radiation, usually for benign uterine lesions. The tumor usually arises from the mucosa of the posterior wall with rapid growth into the uterine cavity. There can be either solitary or multiple growths. The lesion often grossly resembles a benign polyp.

These tumors can not only produce the rhabdomyocyte, as seen in the present case, but also can contain a cartilaginous or osteogenic tumor, liposarcoma, or occasionally an embryonal form. Very often they have a concomitant epithelial component which often has the characteristics of an adenocarcinoma of the endometrium.

Generally the tumor is confined to the uterus when first diagnosed. Although there is predilection for local extension by this neoplasm, lymphatic and hematogenous metastases are not rare. When they occur distant metastases are to the lung, but liver and brain are not exempt. Histogenetically, the mixed mesodermal tumors are thought to arise from multi-potential stromal cells which have the ability to differentiate into either epithe-

Fig. 3—Microscopic appearance of characteristic crossed striations in a mixed mesodermal sarcoma (1000 x).

lium or mesoderm. The mesodermal cells differentiate into various types of tissues, such as striated muscle osteoid or cartilagenous tissue, producing the heterogenous tissues so often seen in mixed mesodermal sarcomas.

Bleeding and discharge are the symptoms that cause these post-menopausal women to seek medical help. The average duration of these symptoms is two months. Abdominal or pelvic pain may be present and when the tumor is advanced, intestinal symptoms and weight loss may be present. About 75% of the patients have enlargement of the uterus when first seen. Nearly 25% have viable tumor extruding from the cervical os at the time of initial examination. Punch biopsy and dilatation and curettage establish the diagnosis in ap-

proximately 50% of the cases. These tumors usually recur within the first year. The five year survival rate is 15 to 20%.

Radiotherapy offers little in the control of these neoplasms. Adequate operation is the treatment of choice. Surgery should include a total abdominal hysterectomy and bilateral salpingo-oophorectomy. Chemotherapy has been of little help.

Dr. Asinger:

Was the bleeding for 25 years secondary to the neoplasm?

Dr. Reichert:

The bleeding for the 25 years was not due to the neoplasm. The malignancy was probably present for less than a year.

"I was once, I remember, called to a patient who had received a violent contusion in his tibia, by which the exterior cutis was lacerated, so that there was a profuse sanguinary discharge; and the interior membranes were so divelicated, that the os or bone very plainly appeared through the aperture of the vulnus or wound. Some febrile symptoms intervening at the same time (for the pulse was exuberant and indicated much phlebotomy). I apprehended an immediate mortification. To prevent which, I presently made a large orifice in the vein of the left arm, whence I drew twenty ounces of blood; which I expected to have found extremely sily and glutinous, or indeed coagulated, as it is in pleuritic complaints; but, to my surprise, it appeared rosy and florid, and its consistency differed little from the blood of those in perfect health. I then applied a fomentation to the part, which highly answered the intention; and after three or four times dressing, the wound began to discharge a thick pus or matter, by which means the cohesion—But perhaps I do not make myself perfectly well understood?"*

*Henry Fielding: Tom Jones, Book VII Chapter XIII 1749.

"The history of science, and in particular the history of medicine... is... the history of man's reactions to the truth, the history of the gradual revelation of truth, the history of the gradual liberation of our minds from darkness and prejudice."

Yeshiva University

I think that there can be a very great distinction between generic drugs and brand name drugs. And that applies to products of original research that have outlived their patent protection as well as to drugs that have long been in the public domain. Let me explain why.

The Importance of the Manufacturing Environment

In terms of formulation, quality control, and the ability to reproduce an essentially identical product, batch after batch, I doubt that many firms are properly equipped to put out a product that is as carefully controlled as the product marketed by a pharmaceutical company with sophisticated research and high quality manufacturing facilities. For example, when a company comes out with its own preparation of a drug that has just lost its patent protection, there is no assurance that the drug it produces will be a therapeutic equivalent. The raw material could be identical and yet bioavailability might vary from complete unavailability to that which is equivalent to the original.

It Isn't Enough to Meet USP and NF Standards

Meeting USP and NF standards is not enough to guarantee therapeutic equivalence. In certain instances, stricter standards must be applied. Right now, the New York Heart Association has a committee that is studying the problem of digoxin equivalent

lency. I am certain that they are going to recommend a bioavailability assay of a particular digoxin. Unless this is done, they will not recommend it for purchase or use in New York City hospitals. It represents too much of a hazard. They have gone so far as to recommend a batch-by-batch certification of bioavailability even though the company has been reproducing and marketing a digoxin product through the years.

The Problem of Controlling Bioavailability of Generics

The FDA does not have the manpower to inspect the quality control capabilities of hundreds of houses specializing in generic products. And I don't think that the average pharmacist is knowledgeable or aware of the quality and bioavailability of the infinite numbers of generic preparations. A recommendation has been made that every time a generic house (or for that matter a large pharmaceutical company) markets an already existing drug for the first time, a modified new drug application should be submitted. The manufacturer would have to show that his compound is the therapeutic equivalent of the standard compound in use, assuming that the standard compound is one that has been available for an extended period—say 15 years. This would be one indication that the control of bioavailability is beginning to get the attention that it deserves.

Clinical Predictability More Important Than Price

Although the question of price has been greatly exaggerated, it is true that patients can often save money on generic drugs. But you are not going to dare attempt to save money if it jeopardizes a patient's health. I turn to the example of cardiac glycosides. In recent years, the cardiac glycosides are probably the most drugs we use with the smallest difference between a maximally safe dose and a toxic dose. If you are dealing with a drug of this type, the concern must be clinical predictability. At the time of variations in bioavailability, it would be silly to try to save the what might amount to maybe \$10 or \$20. The physician cannot age his patient and be sure that the drug prescribed has the positive effect expected. This is especially significant when the patient is on the product, not for the product, but for the rest of his life.

minimize nonequivalence of drug components produced by different manufacturers. Arguments relate largely to the extent of product inequivalences. Experience over the past six years has uncovered a greater incidence of nonequivalence of products prepared by different manufacturers from generically equivalent substances than many had previously surmised.

Newer Bioavailability Studies Reveal Differences

Bioavailability may be defined as a measure of the rate and amount of absorption of a drug substance from its administered dosage form. For several years pharmaceutical scientists have proposed that bioavailability data on presumably equivalent dosage forms provide the best measure of product equivalence—short of adequate clinical trial. In their continued search for shortcuts to the evaluation of product equivalence, medical and pharmaceutical scientists have increasingly relied upon bioavailability characteristics as reflected by blood levels of a drug after its administration to human subjects.

Leading manufacturers now conduct comparative bioavailability studies on their own product dosage forms after production process changes that would have been considered inconsequential a few years ago. This isn't surprising, since there are so many possible differences in production operations that the opportunities for inequiva-

lent generic and brand name products are numerous—even when the production process begins with identical chemical substances. Moreover, reputable manufacturers are striving to improve *in vitro* control measures, such as dissolution characteristics, which are being related more meaningfully to bioavailability reference data.

As a result of advances in scientific instrumentation and analytical methodology which permit measurements of small quantities of drug substances in the body, our abilities to detect differences in bioavailability and possible therapeutic nonequivalence have appreciably improved.

Product Selection

Based on Patient Response
Improved specifications and standards can better assure the equivalence of drug substances. Manufacturers, compendia and regulatory agencies can all play a part. However, it is the drug product, not the drug substance, that the physician, pharmacist, nurse and patient-customer utilize. How can these indi-

viduals make or influence specific product selections to minimize variations in therapeutic equivalence of multisource drugs? Patients' responses to a drug product provide a basis of experience to aid the physician in his selection of a particular product. The nurse and pharmacist can also help detect patient responses, but ultimate responsibility must remain with the physician.

Reputation of Manufacturer as Basis for Product Selection

The physician, to assure that his patients receive quality health care, must rely upon the capabilities of the reputable pharmaceutical manufacturer who is equipped to develop, prepare and control a quality product of uniform, reliable therapeutic performance. Substitution with purportedly equivalent generic products that are only superficially evaluated by an imitator manufacturer can place the health of the patient secondary to factors of price or convenience for the provider.

Opinion & Dialogue

What is your opinion, doctor?
We would welcome your comments.

Integument!

Our skin—the human integument—covers us, defines us, protects us. But skin is subject to cuts, burns, abrasions. And infections. Neosporin Ointment fights infection by providing broad antibacterial action against susceptible skin invaders. It contains antibiotics that are rarely used systemically, reducing the risk of sensitization.

INDICATIONS: *Therapeutically*, used as an adjunct to appropriate systemic therapy for topical infections, primary or secondary, due to susceptible organisms, as in:

- infected burns, skin grafts, surgical incisions, otitis externa
- primary pyodermas (impetigo, ecthyma, sycosis vulgaris, paronychia)
- secondarily infected dermatoses (eczema, herpes, and seborrheic dermatitis)
- traumatic lesions, inflamed or suppurating as a result of bacterial infection.

Prophylactically, the ointment may be used to prevent bacterial contamination in burns, skin grafts, incisions, and other clean lesions. For abrasions, minor cuts and wounds accidentally incurred, its use may prevent the development of infection and permit wound healing.

CONTRAINDICATIONS: Not for use in the external ear canal if the eardrum is perforated. This product is contraindicated in those individuals who have shown hypersensitivity to any of the components.

PRECAUTION: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.

Parathion and Other Organophosphate Pesticides

A Medical Emergency

WARREN R. LAWSON, M.D.*

ABSORPTION OF SUFFICIENT quantities of any of the organophosphate pesticides can cause acute intoxication and create a medical emergency. Entry into the body can be by inhalation, ingestion, or absorption through the skin, with the latter being the most common route of entry for the occupationally exposed. Ingestion is the usual route in accidental, suicidal, or homicidal poisonings. Recent restrictions placed on the use of DDT and the related organochlorine pesticides have resulted in a greater reliance upon the organophosphates for pest control. Thus, the opportunity for exposure and the prospect of poisoning has increased greatly.

The organophosphate pesticides as a chemical family share the capability of inhibiting the cholinesterase activity in man. Thus, the diagnosis, treatment, and prevention of poisoning by these chemicals can be considered collectively. As an aid to recognition of these pesticides a list, in decreasing order of hazard, is presented.

Some Organophosphate Pesticides¹

(Estimate of hazard is based on acute dermal and oral toxicity in animals.)

Most Dangerous

TEPP (Bladan; Kilmite 40; Tetron; Vaportone)
phorate (Thimet)
disulfoton, thiometon; dithiosystox (Di-Syston)
paraaxon (E-600; Mintacol)
thionazin, BSI (Nemafos; Cynem)
parathion (E-605; Alkron; Alleron; Etilon; Thiophos, etc)
demeton (Systox)
mevinphos, ISO, BSI (Phosgene; Phosdrin)
EPN
schradan (OMPA; Pestox III; Sytam)
metacide
methyl parathion (Dalf; Metron; Nitrox 80; etc)
azinphos-methyl (Guthion; Carfene; Guthathion M)
monocrotophos (Azodrin; Nureacron, etc)
dicrotophos (Bidrin; Carbicron; Ektafos, etc)

Dangerous

phosphamidon (Dimecron)
carbophenothion (Trithion; Dagadip; Garrathion)
coumaphos (Co-Ral; Asuntol; Muscatox; Resitox)
dichlorvos, DDVP (Vapona)
diazinon, ISO, BSI (Basudin; Diazide; Garden-tox, etc)
ethion (Nialate; NIA 1240)
delnav, dioxathion (Delnav)

Less Dangerous

methyl demeton (Meta-Systox)
dimethoate (Cygon; Daphene; Trimetion, etc)
naled (Dibrom)
Phostex
dicapthion (Di-Captan)
DEF; DeGreen; Ortho Phosphate Defoliant, etc
trichlorfon, ISO, (Dipterex; Tugon, etc)

Least Dangerous

Chlorthion
Ruelene
malathion (Cythion; Karbofos; Malamar, etc)
ronnel (Korlan; Trolene; Viozene, etc)

Workers in agriculture or agricultural services who regularly use the organophosphate pesticides should recognize the potential hazards of working with these chemicals, take appropriate safety precautions, and be under medical supervision. The medical management of such workers should include a pre-exposure and periodic "cholinesterase blood level activity test." A substantial drop from the pre-exposure cholinesterase level is an indication of abnormal exposure to the organophosphates, requires remedial work procedure action, and calls for a period of medical surveillance for the possible development of symptoms. The test requires only a small amount of blood drawn from a finger prick into a heparinized capillary tube. The Minnesota Department of Health will supply mailing kits containing the heparinized tubes to physicians, will run the tests, and resubmit the findings on request and at no charge. However, the test is such that it can be run by most laboratories without difficulty.

In a medical emergency the cholinesterase blood

*Secretary and Executive Officer, Minnesota Department of Health, Minneapolis, Minnesota.

level activity test is more of confirmatory than diagnostic value. Diagnosis depends upon recognition of the rapidly developing signs and symptoms of illness and a history of exposure. Initially the symptoms are not very specific but usually include abdominal pain, headache, nausea, weakness, diarrhea, vomiting, sweating, and pallor. Later they may also include dyspnea, salivation, lacrimation, muscle twitching, convulsions, cyanosis, shock, and cardiac arrhythmias, coma, and death. A positive alleviation of signs and symptoms following initial treatment with atropine is of confirmatory diagnostic value.

Treatment of organic phosphate poisoning may range from simple removal from exposure and observation for developing symptoms to a very rigorous regimen of action. The first step should be one of self protection of physician and those who must handle the patient, especially if the patient's exposure has come from a spill or contaminated clothing. Then there is need for positive pressure artificial respiration and oxygen if cyanosis is present. When color returns, give 2 to 4 mg of atropine intravenously. It should be noted that this dose is about ten times the amount given for other conditions in which atropine is considered therapeutic. The dose should be repeated every five to 10 minutes until signs of atropinization

appear. This condition should be maintained for 48 hours. In severe cases of poisoning 1000-2000 mg of atropine may be required. Pralidoxime chloride (2 PAM, Protopam), if used during the first 24 hours after poisoning, complements the effect of atropine and hastens the reactivation of cholinesterase enzymes. For adults the initial dose of 1 gm should be injected intravenously at a rate of 500 mg per minute. If muscle weakness is not relieved within an hour the dose should be repeated. After supportive treatment is underway the patient should be decontaminated with soap and water, contaminated clothes should be removed from the area, and the area itself decontaminated.

The Minnesota Department of Health has been actively concerned about the health hazards associated with the use of organophosphate pesticides. It routinely processes several hundred blood samples for cholinesterase activity each year. It has provided contract sprayers with good practice procedures for protection against exposure to the organophosphate pesticides, and it recently co-sponsored a short course entitled "Pesticides and Public Health." Further information, advice, or supportive help can be obtained by contacting the department.

State Health Department Names Assistant Executive Officer

Ellen Z. Fifer, M.D., has been appointed executive officer for programs of the Minnesota Department of Health. The new position was created at the recommendation of the governor's Loaned Executives Action Program (LEAP) as part of a reorganization of the department.

Criteria of Cerebral Death

PRIV. DOZ. DR. C. KÄUFER*

FUNCTIONAL LOSS OF an essential organ initiates the process of dying, leading to disintegration of the whole organism. Death occurs when this stage becomes irreversible. In the Federal Republic of Germany, authorities unanimously regard cerebral death as the decisive criterion for human death.⁹ Knowing when cerebral death occurs is important because a dying patient's organs may be needed for transplantation. The nearer to death the organs are removed, the better the chances for an effective transplantation.

Definition

If cerebral death is defined as the *irreversible functional loss of the whole brain*, that is, cortex and brain stem, then cerebral death coincides with human death, because the personality of man is linked to the functions of his brain. Brain death, therefore, is identical with the death of the individual. If such a stage is reached, resuscitative measures may be stopped, even if the heart is still beating.

This has been difficult for some to accept, since a beating heart has always meant life. To compound the difficulty that the *reliability of diagnostic procedures* for determining brain death has uncertainties. Difficulties can be troublesome when someone has to decide when to remove an organ in order to transplant it.³

Criteria

The sequence to establish cerebral death are generally agreed upon today. Three diagnostic criteria exist.

1. clinical cerebral death
2. the electroencephalogram
3. serial angiography of the large cerebral arteries.

Complete coma, cerebral areflexia and the loss of brain-stem controlled spontaneous respiration determines the clinical picture of cerebral death. Loss of reflexes and complete atony are not es-

sential for the diagnosis. Spinal reflexes and spinal tone may be present or recur after recovery from spinal shock. We therefore talk about cerebral loss of reflexes only, including the complete loss of cerebral reactions to any stimuli.¹⁰

Electroencephalography

Electroencephalography can substantiate neurological findings, but it cannot prove cerebral death. Cerebroelectrical silence characterizes death even when the encephalogram is greatly amplified.

Iso-electrical EEG should not be confused with a flat EEG, as it still is. Flat EEG's occur in about 10% of the healthy population. An iso-electrical EEG obtained under strict conditions reveals a loss of functions of the cerebral cortex without indicating whether this is reversible or permanent. Most of all, such a cortex with electrical silence does not allow any conclusions on the functions of subcortical structures.

Frozen Lake Comparison

Electrical conditions may be compared to a frozen lake, where the surface is still regardless of possible water movements below the ice. The iso-electrical EEG is, therefore, insufficient to indicate brain-stem status. Its value for determining cerebral death is therefore limited. Regardless of the time of an iso-electrical pattern, it can not serve as proof of brain death. All discussions on how long an EEG has to be iso-electrical until cerebral death is proven are therefore fruitless. Long durations of an iso-electrical pattern do not increase its value in the diagnosis.⁵

The EEG is, however, indispensable,⁷ since further investigations, angiography for instance, are not carried out as long as residuals of cortical activity are observed. Thus, the EEG has become the most important indicator for the next diagnostic procedure.

Serial Angiography

Cerebral death is diagnosed with greatest ac-

*University of Bonn Klinik, West Germany.

curacy through the *serial-angiography of the cerebral vessels*. By means of intracranial interruptions of blood flow, angiography shows typical changes indicating loss of brain functions. This diagnostic procedure should, however, not be limited to the distribution area of the internal carotid artery because it is not representative for the state of the brain-stem. The proof of circulatory arrest, therefore, must include vascular supply of cortex and brain-stem. Angiography should include simultaneous or successive filling of the basilar artery via the vertebral-circulation. This postulation is underlined by the observation of a 60 year old female with scarce visual and oculo-motor defects, where the entire cerebral circulation was only maintained via the right vertebral artery. Here both carotid arteries were occluded.

Transfemoral Approach

We carry out the necessary filling of the carotid

and vertebral arteries by transfemoral catheterangiography with selective probing of the four cerebral vessels. In our experience this method is simple and time saving because all vessels may be entered in one procedure. Following cerebral angiography, kidney and hepatic arteries can be filled with the same catheter and by this the topographic situation clarified for prospective transplantations.^{1,6}

Circulatory Stops

Criterion for correct carotid angiography is the delayed but complete filling of the extracranial internal carotid artery following the external carotid artery. The contrast interruption usually occurs in the syphon area. For the vertebral artery, the typical stop is localized at the atlanto-occipital level. Radiological localization of the stop, however, not always occurs in this area or at the base of the skull. Occasionally the stop is

Fig. 1—Carotid angiography in cerebral death: After introducing the Seldinger catheter into the common carotid artery 15 ml of contrast medium are injected. The external carotid artery shows a complete and unchanged filling. The internal carotid artery only shows a delayed filling. There is an abrupt stop of flow in the extracranial part of the internal carotid artery. There is no filling of intracerebral vessels even in late films of the series.

localized in the cervical section of the vessel.

In our experience, stop of cerebral circulation first takes place in the carotid artery while there is still a flow in the vertebral vessels. This may be considerable and even maintain an almost normal EEG even if the carotid vessels are occluded.

While a circulatory interruption can be diagnosed without doubt, the interpretation of angiograms with rudimentary filling presents difficulties. The question is whether the incompletely outlined branches of the middle or posterior cerebral artery may still be regarded as minimal intracranial blood flow, or whether the contrast medium is being pressed into the vessels by the increased injection pressure, simulating a flow.

This pressure-mechanical theory is substantiated by comparative panangiographic series, in which no vascularisation of these areas could be obtained. As, however, the possibility of intracerebral minimal flow cannot be excluded we are careful in judging such rare pictures presently because of the limited experience.

As time elapses from the first registration of an iso-electric EEG, one observes a continuous lowering of the radiological stop. Branches of the internal carotid artery filled at an earlier angiography and their lack of contrast in later controls indicate a progressive increase of cerebrovascular resistance. Circulatory stoppage at the base of the skull or proximal from there represents the final stage of this development, where no filling of smaller cerebral arteries is possible even with increased pressure injections. Therefore, *the timing of angiography* is essential for the diagnosis.

Timing of Angiography

Considering the interval of circulatory arrest between the carotid and vertebral artery, the timing of angiography has shifted from the carotid to the vertebral arteries. It appears unsuitable to perform the study immediately upon obtaining an iso-electric EEG, as intracranial circulation may still be present at that time. It is best carried out when body temperature and blood pressure drop

Fig. 2—Angiogram of the vertebral artery: Normal contrastation in the cervical part of the vessel. Stop of the contrast column at the atlanto-occipital level. No filling of intracranial branches.

and the initially decreased arterio-cerebrovenous oxygen difference rises again.

Conclusions

Since cerebral death can be proven by angiography, we feel that the diagnostic angle of the problem has been solved. We are presently trying to obtain more data by means of a differentiated documentary catalogue and hope to gain important side results, for instance an answer to the question, whether cerebral panangiography alone is permissible. This would make it possible to establish the

diagnosis at an earlier time and enable us to perform organ transplants under even more favorable conditions.

In all these considerations the health of our patients should never be neglected. Intensive treatment is our first aim: it is being continued until brain death has been proven. On the other hand the chance to obtain an organ donor should not be missed in view of the large number of patients in need for organ transplantation. It was the purpose of this presentation to show that brain death can be proven beyond any doubt.

Failure to Diagnose Tuberculosis

A physician treated a patient from December through April for chest congestion and a cold. The patient requested a chest Xray. The physician did not have one taken.

Later, the patient was x-rayed for workmen's compensation purpose for a mild chest injury and was found to have tuberculosis. He was subsequently confined to a sanitarium for a year, lost one year in wages.

The judge directed a verdict in favor of the physician who testified, that tubercu-losis was difficult to diagnose and that treatment of the patient was reasonable under the circumstances. The patient was not allowed to recover damages from the physician.

Psychologically Induced "Scotomata"

White Physician vs. Black Patient

EDWARD W. POSEY, M.D.*

AT THE TURN OF THE century, on a continent where there were few representatives of what is now America's largest racial minority, Sigmund Freud developed a theory for understanding and treatment of psychiatric problems related to the psychosocial ills of the predominantly Jewish and Catholic population of Vienna. Today the method which he proposed is being questioned by those for whom it was to some degree beneficial and even more by those for whom it had virtually no applicability. His technique is not the only means to alleviate the suffering of psychiatric patients.

In 1954, America was suddenly faced with a change in the status quo by the ruling of the Supreme Court to proceed with desegregation of its public schools. This bold step aroused feelings of anxiety, fear, and guilt in the majority; and stimulated the minority to question the system which for more than 300 years had accorded them second class or lower status.

I, a black psychiatrist, am sensitive to problems created by interpersonal stress, to the stresses of our rapidly changing society, and to those created by the psychosocial evil bearing the label of racism.

I think white physicians have "scotomata" when faced with the task of giving total care to minority people; the psyche of the patient is neglected. The expectation is that the minority patient will fit the stereotyped mold of being inferior intellectually, physically, and morally. The patient must be submissive, compliant, passive, and above all, grateful for the services which he is receiving.

Social variables generally influence the mental behavior of any culture. Substandard housing, unemployment, poor recreational facilities, inferior educational and cultural programs, and inadequate delivery of health services adversely affect the minority.

Over-valuation of one group jeopardizes the mental health of others. Cultural disadvantages can be devastating to the mental equilibrium of

minority group members.

Regression to a lower functional level occurs with resultant incapacity due to physical or mental illness. Many patients have masked their marked dependency needs by compensatory life styles. Minority patients, in most instances, have not been able to utilize these defenses because of the limitations imposed by the society in which they have to live. It follows then that the regression becomes intensified in the minority due to their limited coping defenses. They expect the physician, who has always been thought of as the "wise father," to understand their needs. "Scotomata," (in some cases blindness) caused by unrealistic attitudes on the part of the white physician, limits the physician's ability to establish this kind of relationship. Having been made exquisitely sensitive to rejection by the many years of being denied full acceptance in our society, the minority patient either openly rebels or uses passive-aggressive maneuvers to support his position in the struggle to gain acceptance and understanding by his white physician. Unaware of his unconscious racial attitudes, the white physician may assume that the patient is uncooperative and too demanding reinforcing the minority person's paranoid ideation.

White physicians must remember that events such as birth, marriage, and death are emotionally charged experiences in minorities as they are in the lives of the majority. The reason for an unwanted pregnancy in a minority patient may well be due to unexpressed anxiety created by the distinct possibility that after delivery the mother will not be able to provide the new arrival with the necessities of life. Her husband is barely able to provide for those who are already his responsibility. The white physician, who is cognizant of this and other problems of the minority will then consider the realities of his patient's situation rather than attaching to her observable behavior, the label of a more malignant psychiatric disorder.

As with birth, marriage with its many neurotic and intense relationships often creates behavioral change in minorities which to the uninformed ob-

*Veterans Administration Hospital, Minneapolis, Minnesota.

server might appear as a psychiatric problem. Stress contributes to the clinical picture of depression or anxiety.

Death to many people is not considered final. It is the time when the deceased will rest in peace after years of labor in a cruel world where acceptance as a person was never known. The remaining close relatives most likely have ambivalent feelings about their loss. They experience guilt for not sharing the expected attitude of their own subculture as to the deserved final rest of the deceased; and they might be angry because the emotional and financial support which the deceased once was able to give will no longer be available.

It requires psychological sophistication to be-

come aware of these feelings even when one is a part of the accepted group. What can a white physician prescribe when faced with obvious psychiatric problems in minority patients? The minority patient is a fellow human being in need of scientific and medical knowledge and skill to aid in the relief of his suffering. He requires, as the white patient requires, evaluation of areas of stress which if understood might resolve the presenting complaints. All the fluids, antibiotics, and drugs in the medical armamentarium will not heal the wounds or remove the scars of discrimination and prejudice. The eradication of physicians' blind spots where minorities are concerned will decrease the psychiatric problems of the minority.

Death thou has seen
In his first shape on man; but many shapes
Of Death, and many are the wayes that lead
To his grim Cave . . .

Immediately a place
Before his eyes appeard, sad, noysom, dark,
A Lazar-house it seemd, wherein were laid
Numbers of all diseas'd, all maladies
Of gastly Spasm, or racking torture, qualmes
Of heart-sick Agonie, all feavorous kinds,
Convulsions, Epilepsies, fierce Catarrhs,
Intestin Stone and Ulcer, Colic pangs,
Daemoniac Phrenzie, moaping Melancholie
And Moon-struck madness, pining Atrophie,
Marasmus, and wide-wasting Pestilence,
Dropsies, and Asthma's, and Joint-racking Rheums.*

*John Milton: Paradise Lost, Book XI, 466-488. (1667)

Diplomacy is to do and say the nastiest thing in the nicest way.—Isaac Goldberg.

Maybe the patient's self-diagnosis is right. He could have hay fever. But that bright red nasal mucosa, along with the thick discharge and excoriation around the nares, strongly suggests that the main problem is a cold. Hay fever or another form of allergic rhinitis may or may not be an underlying factor.

If a complete history and examination rule out allergic rhinitis, the long-term outlook will be a lot more favorable than his own "diagnosis" would have indicated.

But right now, whether he's got allergic rhinitis or a cold, he's suffering from the same irritat-

ing symptoms of drip, congestion and stuffiness. Try DIMETAPP EXTENTABS®. They're formulated to relieve these symptoms without much chance of causing drowsiness or overstimulation. Your patients will appreciate the 24-hour relief they can get from just one tablet every 12 hours.

Cold or

Allergy?

Whether it's a cold or an allergy, Dimetapp Extentabs® effectively relieve stuffiness, drip and congestion.

INDICATIONS: Dimetapp Extentabs are indicated for symptomatic relief of allergic manifestations of upper respiratory tract disease, such as the common cold, seasonal allergies, sinusitis, rhinitis, conjunctivitis and otitis. In these cases it quickly reduces inflammatory edema, nasal congestion and excessive upper respiratory secretions, thereby affording relief from nasal stuffiness and postnasal drip.

CONTRAINDICATIONS: Hypersensitivity to antihistamines of the same chemical class. Dimetapp Extentabs are contraindicated during pregnancy and in children under 12 years of age. Because of its drying and thickening effect on the lower respiratory secretions, Dimetapp is not recommended in the treatment of bronchospasm. Also, Dimetapp Extentabs are contraindicated in concurrent MAO inhibitor therapy.

WARNINGS: Use in children: In infants

and children particularly, antihistamines in overdosage may produce convulsions and death.

PRECAUTIONS: Administer with care to patients with cardiac or peripheral vascular diseases or hypertension. Until the patient's response has been determined, he should be cautioned against engaging in operations requiring alertness such as driving an automobile, operating machinery, etc. Patients receiving antihistamines should be warned against possible additive effects with CNS depressants

such as alcohol, hypnotics, sedatives, tranquilizers, etc.

ADVERSE REACTIONS: Adverse reactions to Dimetapp Extentabs may include hypersensitivity reactions such as rash, urticaria, leukopenia, agranulocytosis, and thrombocytopenia; drowsiness, lassitude, giddiness, dryness of the mucous membranes, tightness of the chest, thickening of bronchial secretions, urinary frequency and dysuria, papilledema, hypertension, hypotension, headache, dizziness, drowsiness, timidity, incoordination, visual disturbances, mydriasis, CNS depressant and less often stimulant effect, anorexia, nausea, vomiting, diarrhea, constipation and dyspepsia, etc.

HOW SUPPLIED: Light blue Extentabs in bottles of 100 and 300.

Dimetapp Extentabs®

Dimetane® (brompheniramine maleate), 12 mg.; phenylephrine HCl, 15 mg.; phenylpropanolamine HCl, 15 mg.

A-H-ROBINS

A. H. ROBINSON, Inc., Philadelphia, Pa. 19106

when pain goes on... and on... and on—

For the patient with a terminal illness, PAIN past, present, and future can dominate his thoughts until it becomes almost an obsession. The more he is aware of the pain he is now experiencing, the more difficult it is to erase his memory of yesterday's pain, and to allay his fearful anticipation of tomorrow's pain.

Surely the last thing this patient needs is an analgesic containing caffeine to stimulate the senses and heighten pain awareness. A far more logical choice is Phenaphen with Codeine. The sensible formula provides $\frac{1}{4}$ grain of phenobarbital to take the nervous "edge" off, so the rest of the formula can help control the pain more effectively. Don't you agree, Doctor, that psychic distress is an important factor in most of your terminal and long-term convalescent patients?

the analgesic formula that calms instead of caffeinates

Phenaphen[®] with Codeine

Phenaphen with Codeine No. 2, 3, or 4 contains: Phenobarbital ($\frac{1}{4}$ gr.), 16.2 mg. (warning: may be habit forming); Aspirin ($2\frac{1}{2}$ gr.), 162.0 mg.; Phenacetin (3 gr.), 194.0 mg.; Codeine phosphate, $\frac{1}{4}$ gr (No. 2), $\frac{1}{2}$ gr (No. 3) or 1 gr (No. 4) (warning: may be habit forming).

Indications: Provides relief in severer grades of pain, on low codeine dosage, with minimal possibility of side effects. Its use frequently makes unnecessary the use of addicting narcotics. **Contraindications:** Hypersensitivity to any of the components. **Precautions:** As with all phenacetin-containing products, excessive or prolonged use should be avoided. **Side effects:** Side effects are uncommon, although nausea, constipation and drowsiness may occur. **Dosage:** Phenaphen No. 2 and No. 3—1 or 2 capsules every 3 to 4 hours as needed; Phenaphen No. 4—1 capsule every 3 to 4 hours as needed. For further details see product literature.

Ⓜ Phenaphen with Codeine is now classified in Schedule III, Controlled Substances Act of 1970. Available on written or oral prescription and may be refilled 5 times within 6 months, unless restricted by state law.

Relationships between Medical Education in Minnesota and Professional Location*

WINSTON R. MILLER, M.D. AND RUSSELL N. HILL, Ph.D.

PUBLIC SUPPORT has led to the development of two new Medical Schools affiliated with the University of Minnesota and a greatly expanded enrollment at the Medical School on the Minneapolis campus. It is anticipated that a great many, if not most, of the graduates of these schools will practice in Minnesota. Previous studies have shown that about half of the practicing physicians in Minnesota received their M.D. degrees from the University of Minnesota, and that about half of all M.D. graduates of the University of Minnesota had professional locations in Minnesota.¹ Since it is known that the location of internship and/or residency has a significant effect on professional location, this study was undertaken to examine these relationships in some detail.

In a study at the University of Kansas School of Medicine, internship and residency training in Kansas were shown to be "significantly correlated with eventual practice in Kansas."² Of the physicians participating in the study, 45 percent were practicing within 200 miles of their internship location. Of those who completed a residency in Kansas, 50 percent remained in Kansas to practice.

A study of all medical school graduates for the years 1945 and 1950 showed that 59 percent of 1945 graduates were practicing in the same state in which their residency training occurred, compared to 63 percent of 1950 graduates.³ The same

study found that 42 percent of 1945 graduates were practicing in the same state as the location of their internship, compared to 48 percent of 1950 graduates.

Data for the present study were extracted from AMA records on all living physicians who had ever been enrolled in an internship or residency in Minnesota and included the following: the institution and year(s) of enrollment in internship and/or residency, the medical school and year of graduation, the current specialty, and the current address. Current interns and residents were excluded.

Current Location of Previous Minnesota Interns by Year of Internship

Table 1 shows present location of previous interns according to year of internship. Although only 40 percent of all former Minnesota interns are now located in Minnesota, the percentage appears to be considerably higher for 1970-71. The prominent migration to western states (principally California) seems to have decreased sharply since 1960. However, this decrease was counter-balanced by an increase of migration to eastern states and other countries. Furthermore, there was a decrease in retention of physicians within Minnesota.

Current Location of Previous Minnesota Interns by Internship Institution

Data in Table 2 show little differences in geographic distribution among alumni of the different institutions except for the 19 alumni of the re-

*This study was supported by HEW Grants 5 GO3 RM-00021 to Northlands Regional Medical Program, Inc. Opinions represent views of the authors and do not constitute endorsement by HEW or NRMP. Dr. Miller is Program Director of NRMP; Dr. Hill is Evaluation and Data Officer.

TOTAL (N=5963)	40	19	8	9	22	3

Current Location of Previous Minnesota Residents by Year of Residency

The geographic distribution for residents was similar to that for interns (Table 3), showing a decrease in migration to the West since 1960, an increase to the East and other countries, and a decrease in retention in Minnesota. Relatively more residents than interns migrated to southern states, but the over-all average retention in Minnesota was identical.

Current Location of Physicians Enrolled in More Than One Component of Medical Education in Minnesota

Sixty-four percent of Minnesota M.D. graduates who also took internships and residencies in Minnesota have remained in the state (Table 5). Nearly as many Minnesota graduates stayed if they had either an internship or a residency in Minnesota. Nearly half of out-of-state graduates with an internship and a residency in Minnesota are

TOTAL (N=6263)	40	15	9	12	19	5

Current Location of Previous Minnesota Residents by Institution

Hennepin County Hospital showed the highest percentage retention of former residents, and the Mayo Clinic showed the lowest (Table 4). The 22-point difference suggests fundamental differences between these institutions. However, when the actual numbers of physicians are compared, the Mayo Clinic contributed 758 physicians to the Minnesota pool while Hennepin County Hospital contributed 166. The University of Minnesota, with 45 percent retention, contributed the largest number—785. Differences in location in other

still located in the state. This percentage is similar to the overall retention of graduates of the University of Minnesota School of Medicine.¹

Current Location of Previous Minnesota Residents by Specialty

Over 50 percent retention occurred in the specialties of Therapeutic Radiology, Physical Medicine, and Obstetrics-Gynecology (Table 6). Less than 30 percent retention occurred in Thoracic Surgery, Plastic Surgery, Orthopedic Surgery, Dermatology and Unspecified Specialty.

All remaining specialties fell within a plus or minus range of 10 percent around the average c

40 percent. When data on the *Primary Physician Specialties* of General Practice, General Internal Medicine, General Pediatrics and Obstetrics-Gynecology were combined, the retention percentage was 43.1 percent—3.3 percent above the overall average. Only 30 percent of all specialties were in these four primary fields.

Discussion

A previous study showed that about one-half of all graduates of the University of Minnesota Medical School located somewhere in Minnesota.¹ This study shows that when Minnesota M.D. graduates enrolled in *either* an internship *or* a residency in Minnesota, retention rose to 60 percent. When they enrolled in *both* an internship *and* a residency, retention rose to 64 percent. Nearly half of all graduates from other medical schools who enrolled in *both* an internship *and* a residency in Minnesota remained in the state—a total of 1137 physicians.

When internship and residency enrollments were considered separately without regard to school of graduation, only a 40 percent retention occurred in each group. Studied over time, the data showed remarkable similarity for periods covering more than four decades. Retention

dropped moderately in the 1940's and in the 1960's, but seemed to rise markedly for the one year of 1970-71. The significance of the latter may be questioned due to the frequent AMA time lag for updating current addresses.

Moderate differences occurred between the various institutions. Hennepin County Hospital, reputed to have close relationships with both the practicing and the academic communities, had the highest percentage retention. The Mayo Clinic, noted for its national and international reputation, had the lowest percentage retention. However, numerically the Mayo Clinic was second only to the University of Minnesota (758 and 785 respectively).

Physicians who did not locate in Minnesota are widely distributed all over the United States and in foreign countries. Only about one-fourth of them are located in the Middle West. The West attracted many physicians who had trained in Minnesota during the years of heavy westward migration. This was apparently not just a western attraction, for when western migration decreased in the 1960's, increased migration occurred to other areas.

Analysis of location by specialty showed simi-

lar retention percentages for most of the 37 different specialists. The data do not indicate that Minnesota has been training excessive numbers of subspecialists for location in other areas of the country.

Minnesota seems to have accepted a social imperative to train more physicians and to retain as many of them as possible for practice in the state. Although combined emphasis on complete undergraduate and graduate education, *in* Minnesota and *for* Minnesotans, would probably help to achieve this goal, the ultimate desirability of a professional pool consisting almost entirely of

locally trained physicians may be open to question. Many educators and practitioners feel that a mixture of educational backgrounds is desirable for an optimum pool of any kind of professional. Fifty percent retention of graduates of other medical schools warrants continuation and even expansion of these programs. Expansion of graduate educational opportunities for Minnesota graduates should probably not be achieved by preferential selection, thus reducing the number of positions offered for out-of-state graduates. There is an evident need for an absolute increase in opportunities for graduate medical education.

See References 1-3 on page 336.

120th Annual Meeting
Minnesota State Medical Association
Preliminary Scientific Program Synopsis
May 24 and 25
Raddisson South-Minneapolis

(Continued from page 266)

May 25: Daily Practice in Society

Clinical practitioners and behavioral scientists will discuss the problems of practicing medicine in contemporary society.

- 9:00-10:30 a.m. *Session V: Patient Education: The Basis of Quality Practice*
Session Leader: Donnell D. Etzwiler, M.D., Clinical Assistant Professor of Pediatrics, University of Minnesota, Minneapolis
- Experience in a prototype of patient education: Diabetes Education Center, Minneapolis
 - How to use current educational concepts and methods in designing patient education in your practice
 - Physicians, health educators, patients, and third-party payers, cooperating for improved health care
- 11:00-12:20 a.m.-p.m. *Session VI: Children in Trouble: The Early Years*
Session Leader: Francis S. Wright, M.D., Associate Professor of Pediatric Neurology, University of Minnesota, Minneapolis
- Developmental problems, behavior disorders, learning difficulty, and family stress syndromes as they affect the treatment of children
 - Early identification and appropriate management
- 1:40- 3:00 p.m. *Session VII: Problems of Aging*
Session Leader: Floyd K. Garetz, M.D., Associate Professor of Psychiatry, University of Minnesota, Minneapolis
- Psychological changes, common psychiatric problems, medical gerontology, the inner life of the aged
 - Medical management of an aged population
- 3:30- 5:00 p.m. *Session VIII: The Personal Life of the Physician*
- 1:40- 2:20 *Session IX: Medical, Psychological and Social Hazards of the Abortion*
Session Leader: Fred E. Mecklenburg, M.D., Obstetrics-Gynecology, Minneapolis
- 2:20- 3:00 *Session X: Preabortion and Postabortion Counseling*
Session Leader: Fred A. Lyon, M.D. Obstetrics-Gynecology, Minneapolis
- 3:30- 5:00 *Session XI: The Abortion Procedure*
Session Leader: P. Theodore Watson, M.D., Obstetrics-Gynecology, St. Paul
- The abortion procedure in the first trimester, Jane E. Hodgson, M.D., St. Paul
 - The abortion procedure in the second trimester, Robert Goodlin, M.D., Stanford

Classified advertising rates are thirty (30) cents a word; minimum monthly charge \$7.50; key number, fifty (50) cents additional.

Replies to advertisements with key numbers should be mailed in care of Minnesota Medicine, 375 Jackson, St. Paul, Minn. 55101.

WAYZATA MEDICAL BUILDING OFFICE SUITES—Located in the fastest growing suburban area in the Twin Cities. We offer:

- Surrounding area of lakes, country clubs, woods, beautiful homes;
- Unsurpassed medical building facilities
- Fast growing area—high median family incomes
- Beautiful building—inside and out
- Inner courtyard with trees and landscaping
- Heated indoor parking
- Adjacent access to freeway system
- Low rental rates—favorable base terms
- Financial services

We have grown to fourteen specialties since our building was completed two years ago. We particularly are interested in Orthopedics, Psychiatry, Urology, Otolaryngology, Internal Medicine and Dentistry. Give us a call. We have a lot more to show you and to talk about. Reply to: Mr. Paske, Wayzata Medical Building, 250 North Central Avenue, Wayzata, Minn. 55391, (612) 473-0031.

ASSOCIATE FOR AAFP member in professional corporation or expense and call sharing association. New clinic building in construction to serve three rural communities. Immediate partnership in corporation, if desired. All corporate benefits immediately. Located in beautiful Hiawatha Valley of southeastern Minnesota, 35 miles from Mayo Clinic and 55 miles from Gunderson Clinic. Contact R. L. Sauer, M.D., Root River Valley Medical Clinic LTD., Box 496, Preston, Minnesota 55965.

ASSOCIATES WANTED: Family doctors to join a growing Family Practice Department in a large multiple specialty medical center, Minneapolis suburb. Excellent opportunity for teaching undergraduate and graduate students in Family Practice. Four man department with excellent growth potential. Reply to Dr. Harley J. Racer, Chairman Family Practice Department, St. Louis Park Medical Center, St. Louis Park, MN 55416. Telephone 612-927-3320.

FAMILY PRACTITIONER for rural area as member of 22 man multispecialty medical and surgical group. Opportunity for rural practice which incorporates advantages of membership in an urban medical group. Includes: *Educational programs:* Conferences, paid medical meetings, hospital rotations, peer review and support; *Quality Medical Care:* Ease of consultation, excellent lab and X-ray, regular call schedule and time off; *Economic Benefits:* Adequate salary, year end bonus, pension plan, group disability, life insurance. Write 210 Ninth Street S.E., Rochester, Minnesota; or phone collect, J. J. Garber, M.D., 507-288-3443.

G.P. OR INTERNIST. 40 hour week, no night calls, mainly examining executive and professional people. Easily arranged vacation time or time for varied pursuits. Must be 60 or below, but special provision can be made for orthopedic, cardiac or respiratory impairments. \$30,000 base. Write MIN-

NESOTA MEDICINE—479, 375 Jackson, St. Paul 55101.

GENERAL PRACTITIONER needed as associate in county seat community of 2,000. Modern 35 bed hospital 4 blocks from fully equipped clinic. An excellent opportunity to live the good life in rural Minnesota. Write: Minnesota Medicine-477, 375 Jackson St., St. Paul 55101.

GENERAL PRACTITIONER desired for northern Minnesota clinic located near Lake of the Woods area. Enjoy the clean air, clear waters, compatible working arrangements including ample time off for meetings, vacations and good financial arrangements. Excellently equipped hospital (acute, skilled nursing and board and care facilities). Fine clinic one block from hospital. Write: MINNESOTA MEDICINE, 473, 375 Jackson St., St. Paul 55101.

TWELVE MAN multispecialty clinic needs general practitioners ophthalmologists, otolaryngologists and internists. The present group includes surgeons, internist, urologist, gynecologist and generalists with family practice background. Northeastern Minnesota location with complete hospital facilities, excellent recreational country both winter and summer. Complete school system through junior college. Solid economic conditions. No big city problems. Profit sharing plan and pension plan. Beginning salary \$30,000 a year. Ownership participation after two years. Write MINNESOTA MEDICINE-478, 375 Jackson, St. Paul 55102.

FOR SALE—Fully equipped office (nurse and receptionist) in Tracy, Minn. May move right in to a busy lucrative practice. For complete details, R. O. Schroepfel, M.D., Tracy, Minn. 507-629-4211.

SOUTHWEST MINN. HEALTH CARE ENTERPRISE—Six communities working together to recruit physicians to implement model rural health care program designed by and affiliated with Univ. of Minnesota, Dept. of Family Practice. New clinic available, estimated 15,000 in model area, 3 nursing homes, plus other normal attributes of top rural farming area. Contact: Wallace W. Nelson, Lamberton, Minn. 56152. Tele: 507-752-7372.

YOUNG family practitioner(s) wanted. Three doctor clinic built 1973 by 30 year old doctor. New hospital in town. 35 miles south Minneapolis. Early partnership. Salary plus incentive bonus. John Berg, M.D., New Prague, Minnesota 56071.

SHELL LAKE CLINIC, LTD., Shell Lake, Wisconsin, expanding to seven man group. Three family physicians and one surgeon desire additional two family physicians and one internist. New 70 bed general hospital adjoins clinic. Excellent remuneration in corporate practice. City surrounds one of largest and finest swimming and fishing lakes in Northwest Wisconsin. Call 715-468-2711 or write to Clinic Manager Darrell Bailey.

Alcoholism

Some Dynamics and Goals in Treating Alcoholism

REV. VERNON E. JOHNSON, D.D.*

"THE ALCOHOLIC is in a clash by himself," aptly describes the problem. There is loneliness, desocialization from others, plus internal conflict. A set of unpredictable or compulsive behavior clashing repeatedly with his values cause this conflict.

Treatment at St. Mary's Hospital rests on these premises: (1) First, dependence upon alcohol results in self-destructive, or other-destructive behavior. The goal is to isolate this problem—this pathologic relationship to chemicals—throughout the treatment. (2) Two, a rigid set of defense mechanism blocks the patient's insight into his harmful relationship to the chemical. (3) Three, distortion of memory, coma, or blackout may further impair the patient's insight. (4) Subconscious moral conflict progressively burdens him with anxiety and guilt. This causes him to drink to feel normal."

Treatment Design

The treatment design, then, sets itself to meet and to deal with this pathology in the following ways: (1) First identification of the chemical dependency syndrome. One important goal here is the removal of the feelings of uniqueness which the patient has upon arrival. This is done through a series of lectures, films, and recommended reading.

2. The treatment seeks to have the patient identify and accept the specific forms of defenses he uses to impair his judgment which lock him in stereotyped self-destructive behavior. Peer-group therapy sessions held two hours daily help him recognize these defenses.

One-to-one counseling sessions help him eval-

uate his defensiveness.

3. When his defenses have been breached, and his negative emotional life is exposed, the final phase of this portion of treatment is entered, namely, the patient's identification and acceptance of the reality of his own specific negative and destructive attitudes.

This is accomplished chiefly within the peer-group sessions each day, wherein other patients and the counselor confront by description such attitudes as hostility, fear, self-pity, and resentment.

Whenever possible, persons close to the patient are included in sessions with counselor and patient. Regular one-to-one sessions with the counselor are held.

The goal is to have the patient recognize that his moral conflicts are the signs of his sickness, that upon their resolution depends his recovery, that he must enter consciously and consistently into behavior patterns which are agreeable to his value system, and that he regains adequate ego strength and emotional health.

Outpatient Program

St. Mary's plan includes a two-year outpatient program of treatment.

In this period, the patient is encouraged to make use of the counseling available. He is assigned with his spouse to a weekly therapy group designed around the goals of rehabilitation. He is encouraged to affiliate with Alcoholics Anonymous, the principles of which he was introduced to as an inpatient.

From the day of his admission to hospital to the conclusion of the outpatient period, he is seen as moving from a locked-in negative internal environment toward the freedom of a normal range of feelings and emotions.

*President of the Johnson Institute which is consultant to Alcoholism Unit, St. Mary's Hospital, Minneapolis.

Given as part of a Symposium on the "Treatment of the Hospitalized Alcoholic" which was presented to the combined meeting of the Mayo Clinic Staff and the Zumbro Valley Medical Society on November 4, 1970.

The greatest truths are the simplest; and so are the greatest men.—J. C. and A. W. Hare.

^{new}
SantylTM
ointment
(collagenase)

Indications: Santyl Ointment is indicated for debriding dermal ulcers and severely burned areas. In other types of necrotic skin lesions reports on the use of Santyl Ointment have been limited to clinical observations without controls.

Contraindications: Application is contraindicated in patients who have shown local or systemic hypersensitivity to Collagenase.

Precautions: The enzyme's optimal pH range is 7 to 8. Lower pH conditions have a definite adverse effect on the enzyme's activity, and appropriate precautions should be taken.

The enzymatic activity is also adversely affected by detergents and hexachlorophene and heavy metal ions such as mercury and silver which are used in some antiseptics. When it is suspected such materials have been used, the site should be carefully cleansed by repeated washings with normal saline before Santyl Ointment is applied. Soaks containing metal ions or acidic solutions such as Burow's solution should be avoided because of the metal ion and low pH. Cleansing materials such as hydrogen peroxide or Dakin's solution do not interfere with the activity of the enzyme.

Deilitated patients should be closely monitored for systemic bacterial infections because of the theoretical possibility that debriding enzymes may increase the risk of bacteremia.

The ointment should be confined to the area of the lesion in order to avoid the risk of irritation or maceration of normal skin.

A slight erythema has been noted occasionally in the surrounding tissue particularly when the enzyme ointment was not confined to the lesion. This can be readily controlled by protecting the healthy skin with a material such as Lassar's paste.

Since the enzyme is a protein, sensitization may develop with prolonged use although none has been observed to date.

Adverse Reactions: Adverse reactions to Collagenase have not been noted when used as directed.

Dosage & Administration: Santyl Ointment should be applied once daily (or once every other day in the case of outpatients) in the following manner.

(1) Prior to application the lesions should be gently cleansed with a gauze pad saturated in normal saline, buffer (pH 7.0-7.5) or hydrogen peroxide to remove any film and digested material.

(2) Whenever infection is present, as evidenced by positive cultures, pus, inflammation or odor, it is desirable to use an appropriate topical antibacterial agent. Neomycin-Bacitracin-Polymyxin B (Neosporin) has been found compatible with Santyl Ointment. This antibiotic should be applied to the lesion in powder form or solution prior to the application of Santyl Ointment. Should the infection not respond, therapy with Santyl Ointment should be discontinued until remission of the infection.

(3) Santyl Ointment should be applied (using a wooden tongue depressor or spatula) directly to deep wounds, or, when dealing with shallow wounds, to a sterile gauze pad which is then applied to wound. The wound is covered with sterile gauze pad and secured with clear tape or Kling bandage.

(4) Crosshatching thick eschar with a #11 blade is helpful. It is also desirable to remove as much loosened detritus as can be done readily with forceps and scissors.

(5) All excess ointment should be removed each time dressing is changed.

(6) Use of the ointment should be terminated when sufficient debridement of necrotic tissue has taken place.

Overdose: Action of the enzyme may be stopped, should this be desired, by the application of Burow's solution U.S.P. (pH 3.6-4.4) to the lesion.

How Supplied: Santyl Ointment contains 250 units of Collagenase enzyme per gram of white petrolatum U.S.P. The potency assay of Collagenase is based on the digestion of undenatured collagen (from bovine Achilles tendon) at pH 7.2 and 37° C. for 24 hours. The number of peptides cleaved are measured by reaction with ninhydrin. Peptides released by a trypsin digestion control are subtracted. One net Collagenase unit will solubilize ninhydrin reactive material equivalent to 4 micromoles of Leucine.

^{new} SantylTM (collagenase) ointment

"...it may prove to be the drug of choice for wound debridement."

Varma A O et al: *Surg. Gynec. Obstet.* 136:281, Feb. 1973.

To permit healing like this...you want to start like this.

Artist's conception of decubitus ulcer

SantylTM (collagenase) for dermal ulcers and burns:
The first topical enzyme

To attack

...inertive collagen, a substance that is ordinarily resistant to all common topical enzymes used in wound debridement

To dissolve

...the strands of tissue that "anchor" necrotic debris and burn eschar to the wound surface

To effectively remove

...the debris that hinders healing...with simple, once-a-day application

I treat patients with dermal ulcers and burns, and I would like to receive:

- ☐ clinical reprints and scientific information on Santyl.
- ☐ a free in-service training program on the use of Santyl.

A Short Refresher Course In Occupational Medicine

Wisconsin Center, 702 Langdon Street

Madison, Wisconsin

June 1 and 2, 1973

The purpose of this symposium is to update physicians in several highly important and selected fields of occupational medicine. Emphasis will focus on practical topics of greatest current concern, including clinical discussions. All physicians, particularly family physicians, and other specialists who serve industry on a part-time or other basis will be especially interested in this symposium.

For more information, write or call: Carl Zenz, M.D., Medical Director, Allis-Chalmers Corporation, P.O. Box 512, Milwaukee, Wisconsin 53201 (414)-475-4566.

Pre-registration: \$20.00 (includes luncheon and dinner). No registration fee required from students, interns or residents. Enrollment limited to 75.

Make checks payable to: American Academy of Occupational Medicine.

Mail checks to: Mrs. Linda Klatt, Medical Department, Allis-Chalmers Corporation, P.O. Box 512, Milwaukee, Wisconsin 53201.

This course is approved for nine credit hours by the American Academy of Family Physicians.

STATE MEDICAL ASSOCIATION

MAY 1973

Everybody experiences psychic tension.

Most people can handle this tension.

Some people develop excessive psychic tension and need your counseling.

and a few may need counseling
and the psychotropic action of Valium® (diazepam).

Before deciding to make Valium (diazepam) part of your treatment plan, check on whether or not the patient is presently taking drugs and, if so, what his response has been. Along with the medical and social history, this information can help you determine initial dosage, the possibility of side effects and the ultimate prospects of success or failure.

While Valium can be a most helpful adjunct to your counseling, it should be prescribed only as long as excessive psychic tension persists and should be discontinued when you decide it has accomplished its therapeutic task. In general, when dosage guidelines are followed, Valium is well tolerated (see Dosage). For convenience it is available in 2-mg, 5-mg and 10-mg tablets.

Drowsiness, fatigue and ataxia have been the most commonly reported side effects.

Until response is determined, patients receiving Valium should be cautioned against engaging in hazardous occupations requiring complete mental alertness, such as driving or operating machinery.

Roche Laboratories
Division of Hoffmann-La Roche Inc.
Nutley, N.J. 07110

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anti-convulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect.

Adults: Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. **Geriatric or debilitated patients:** 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) **Children:** 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 100 and 500. All strengths also available in Tel-E-Dose® packages of 1000.

Valium® (diazepam)

Sally's back in sew biz! After an arthritic flare-up.

Butazolidin® alka Geigy

Each capsule contains:
100 mg. phenylbutazone USP
100 mg. dried aluminum hydroxide gel USP
150 mg. magnesium trisilicate USP

If it doesn't work in a week, forget it.

including aplastic anemia, may occur suddenly despite regular hemograms, and may become manifest days or weeks after cessation of drug. Any significant change in total white count, relative decrease in granulocytes, appearance of immature forms, or fall in hematocrit should signal immediate cessation of therapy and complete hematologic investigation. Unexplained bleeding involving CNS, adrenals, and G.I. tract has occurred. The drug may potentiate action of insulin, sulfonyleurea, and sulfonamide-type agents. Carefully observe patients taking these agents. Nontoxic and toxic goiters and myxedema have been reported (the drug reduces iodine uptake by the thyroid). Blurred vision can be a significant toxic symptom worthy of a complete ophthalmological examination. Swelling of ankles or face in patients under sixty may be prevented by reducing dosage. If edema occurs in patients over sixty, discontinue drug.

Precautions: The following should be accomplished at regular intervals: Careful detailed history for disease being treated and detection of earliest signs of adverse reactions; complete physical examination including check of patient's weight; complete weekly (especially for the aging) or an every two week blood check; pertinent laboratory studies. Caution patients about participating in activity requiring alertness and coordination, as driving a car, etc. Cases of leukemia have been reported in patients with a history of short- and long-term therapy. The majority of these patients were over forty. Remember that arthritic-type pains can be the presenting symptom of leukemia.

Adverse Reactions: This is a potent drug; its misuse can lead to serious results. Review detailed information before beginning therapy. Ulcerative esophagitis, acute and reactivated gastric and duodenal ulcer with perforation and hemorrhage, ulceration and perforation of large bowel, occult G.I. bleeding with anemia, gastritis,

epigastric pain, hematemesis, dyspepsia, nausea, vomiting and diarrhea, abdominal distention, agranulocytosis, aplastic anemia, hemolytic anemia, anemia due to blood loss including occult G.I. bleeding, thrombocytopenia, pancytopenia, leukemia, leukopenia, bone marrow depression, sodium and chloride retention, water retention and edema, plasma dilution, respiratory alkalosis, metabolic acidosis, fatal and nonfatal hepatitis (cholestasis may or may not be prominent), petechiae, purpura without thrombocytopenia, toxic pruritus, erythema nodosum, erythema multiforme, Stevens-Johnson syndrome, Lyell's syndrome (toxic necrotizing epidermolysis), exfoliative dermatitis, serum sickness, hypersensitivity angitis (polyarteritis), anaphylactic shock, urticaria, arthralgia, fever, rashes (all allergic reactions require prompt and permanent withdrawal of the drug), proteinuria, hematuria, oliguria, anuria, renal failure with azotemia, glomerulonephritis, acute tubular necrosis, nephrotic syndrome, bilateral renal cortical necrosis, renal stones, ureteral obstruction with uric acid crystals due to uricosuric action of drug, impaired renal function, cardiac decompensation, hypertension, pericarditis, diffuse interstitial myocarditis with muscle necrosis, perivascular granulomatous, aggravation of temporal arteritis in patients with polymyalgia rheumatica, optic neuritis, blurred vision, retinal hemorrhage, toxic amblyopia, retinal detachment, hearing loss, hyperglycemia, thyroid hyperplasia, toxic goiter, association of hyperthyroidism and hypothyroidism (causal relationship not established), agitation, confusional states, lethargy; CNS reactions associated with over-dosage, including convulsions, euphoria, psychosis, depression, headaches, hallucinations, giddiness, vertigo, coma, hyperventilation, insomnia; ulcerative stomatitis, salivary gland enlargement. (B)98-146-070-G

Serious side effects do occur. Select patients carefully (particularly the elderly) and follow them closely in line with the drug's precautions, warnings, contraindications and adverse reactions.

For complete details, including dosage, please see full prescribing information.

GEIGY Pharmaceuticals
Division of CIBA-GEIGY Corporation
Ardley, New York 10502

What should a medication for sleep be expected to provide?

Before prescribing Dalmane (flurazepam HCl), please consult Complete Product Information, a summary of which follows:

Indications: Effective in all types of insomnia characterized by difficulty in falling asleep, frequent nocturnal awakenings and/or early morning awakening; in patients with recurring insomnia or poor sleeping habits; and in acute or chronic medical situations requiring restful sleep. Since insomnia is often transient and intermittent, prolonged administration is generally not necessary or

recommended.

Contraindications: Known hypersensitivity to flurazepam HCl.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness (e.g., operating machinery, driving). Use in women who are or may become pregnant only when potential benefits have been weighed against possible hazards. Not recommended for use in persons under 15 years

of age. Though physical and psychological dependence have not been reported at recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage.

Precautions: In elderly and debilitated patients, initial dosage should be limited to 1 mg to preclude oversedation, dizziness, or ataxia. If combined with other drugs having hypnotic or CNS-depressant effects, consider potential additive effects. Employ usual precautions in patients who are severely depressed, or with

Sleep for 7 to 8 hours without need to repeat dosage during the night

No sleep medication has been as rigorously evaluated in the sleep research laboratory as Dalmane. Insomnia patients given one 30-mg capsule of Dalmane at bedtime, on average: fell asleep within 17 minutes, had fewer nighttime awakenings, spent less time awake after sleep onset, and slept for 7 to 8 hours with no need to repeat dosage during the night.

Sleep with consistency

Dalmane (flurazepam HCl) has been shown to be consistently effective even during consecutive nights of administration. Thus there is little likelihood for the need to increase dosage to maintain therapeutic effect.

Dalmane is in a class by itself. Not a narcotic, barbiturate or methaqualone, Dalmane is the only available benzodiazepine specifically indicated for insomnia.

Sleep with relative safety

Chronic tolerance studies have confirmed the relative safety of Dalmane (flurazepam HCl); no depression of cardiac or respiratory function was noted in patients administered recommended or higher doses for as long as 90 consecutive nights. In most instances when adverse reactions were reported they were mild, infrequent and seldom required discontinuance of therapy. Morning "hang-over" with Dalmane has been relatively infrequent. Dizziness, drowsiness, lightheadedness and the like have been the side effects noted most frequently, particularly in the elderly and debilitated. (An initial dose of Dalmane 15 mg should be prescribed for these patients.)

When your evaluation of insomnia indicates the need for a sleep medication, consider Dalmane—a single entity agent proved effective and relatively safe for relief of insomnia.

DALMANE[®] (flurazepam HCl)

When restful sleep is indicated

One 30-mg capsule h.s.—usual adult dosage
(15 mg may suffice in some patients).

One 15-mg capsule h.s.—initial dosage for elderly or debilitated patients.

ROCHE

ROCHE LABORATORIES
Division of Hoffmann-La Roche Inc.
Nutley, New Jersey 07110

Depression or suicidal tendencies. Blood counts and liver and kidney tests are advised during therapy. Observe usual precautions in presence of impaired renal or liver function.

Reactions: Dizziness, drowsiness, lightheadedness, staggering, ataxia may have occurred, particularly in elderly or debilitated patients. Severe drowsiness, lethargy, disorientation and probably indicative of drug intolerance or overdosage, have been reported.

Also reported were headache, heartburn, upset stomach, nausea, vomiting, diarrhea, constipation, GI pain, nervousness, talkativeness, apprehension, irritability, weakness, palpitations, chest pains, body and joint pains and GU complaints. There have also been rare occurrences of sweating, flushes, difficulty in focusing, blurred vision, burning eyes, faintness, hypotension, shortness of breath, pruritus, skin rash, dry mouth, bitter taste, excessive salivation, anorexia, euphoria, depression, slurred speech,

confusion, restlessness, hallucinations, and elevated SGOT, SGPT, total and direct bilirubins and alkaline phosphatase. Paradoxical reactions, e.g., excitement, stimulation and hyperactivity, have also been reported in rare instances.

Dosage: Individualize for maximum beneficial effect. *Adults:* 30 mg usual dosage; 15 mg may suffice in some patients.

Elderly or debilitated patients: 15 mg initially until response is determined.

Supplied: Capsules containing 15 mg or 30 mg flurazepam HCl.

"Too many doctors are indifferent to the economic consequences of their decisions." So stated a recent issue of *Medical News Report* (December 4, 1972), an independent weekly newsletter published by the AMA Chief Executive F. J. L. Blasingame, M.D.

Doctor, are you indifferent...?

In discussing an anticipated increase in Blue Shield rates, Dr. Blasingame's newsletter had this to say:

"In general, it can be said, I have given the impression they are not particularly concerned with the increase in cost of health care to patients..."

"True, an MD's training is primarily scientific, but in the real world of practice, all of his scientific decisions have a price tag, or an economic impact. The economics of health beckon the practitioner's attention. Concern for economics of medicine..."

When the pharmacist recommends that a drug product other than the one ordered be dispensed, the prescriber invariably permits the change when he feels the best interests of the patient will be served.

Shortcomings of Pro-Substitution Argument

The fact remains that it is necessary for the prescriber to know that the change is being contemplated and to be in a position to consent or demur. Without that opportunity for unilateral decision of the pharmacist made in the absence of clinical knowledge of the patient, could expose to needless risks, and in addition jeopardize the relationship between the professions of Pharmacy and Medicine. In my view, there is nothing in the pro-substitution argument that offsets these risks.

The Issue of Drug Knowledge

Substitution advocates claim that the primary justification for changing the rules is the desire to better utilize pharmacists' knowledge about drugs. Yet the pharmacist's task to keep current on the entire field of drug therapy, to some degree puts him at a disadvantage. Most often, a practicing physician will use expert knowledge of no more than 25

be an obligation of medical care...

Medical societies ought to continue campaigns to point out the substantial savings that could be realized thru deductible insurance protection for catastrophic illness. At the very least, they should, in the patients' interest, question the wisdom of any insurance organization that raises health care costs by forcing policyholders to buy insurance they may not need or want and probably won't ever use.

Too many doctors are indifferent to the economic consequences of their decisions. Too many, for example, habitually hospitalize patients for the convenience of the MD. It's no surprise to deny such habits exist... Doctors, thru their medical societies, have unhesitatingly appealed to their patients for support in the fight against government interference in the private practice of medicine. The public in the past has responded. It's time the American Medical Association and state and local medical societies paid off the debt by taking effective action to hold down the cost of medical care."

Cost of Drugs

Insurance rates and hospital charges are only two factors in health

care costs. The cost of drugs—both prescription and nonprescription—is another.

And when it comes to drug costs, the nation's pharmacists are concerned. Through their national professional society, the American Pharmaceutical Association, pharmacists are advising the public to use nonprescription medication cautiously and conservatively, and to seek the advice of their pharmacist before selecting or purchasing such drugs.

Outdated Laws

The pharmacist also is aware that when it comes to prescription drugs, often he has an even greater opportunity to reduce the cost to the patient—with no sacrifice in the quality of the medication dispensed. But in many states, outdated and antiquated laws prevent the pharmacist from engaging in drug product selection. "Drug product selection" simply means that the pharmacist functions in the patient's interest by consciously choosing, from the multiple brands available, a low-cost quality brand of the specific drug to be dispensed in response to the physician's prescription order.

Much *misinformation* has been purposely spread by those who stand to gain financially by maintaining

high drug costs to the public. An endless stream of propaganda has emanated from the drug industry in an effort to persuade the medical profession that these so-called anti-substitution laws should be retained. And as long as these laws are retained, the drug industry will continue its current marketing practices which contribute unnecessarily to high drug costs to patients. These practices also are inviting government agencies to expand their restrictive controls on physicians and pharmacists.

APhA Efforts

As pharmacists, we are concerned about health care costs. We hope that every physician shares our concern on this vital issue, and will give his personal support to the constructive efforts APhA has undertaken in the interest of all patients.

(For a complete discussion of drug product selection, you are invited to request a free copy of the "White Paper on the Pharmacist's Role in Product Selection" from: American Pharmaceutical Association, 2215 Constitution Avenue, N.W., Washington, D.C. 20037.)

Drugs that he selects to treat the variety of conditions encountered in practice. Moreover, the physician's choice of a specific brand is based on his knowledge of the patient's medical history and current condition, and his experiences with a particular manufacturer's product.

Some substitution proponents have argued that the dispensing of a prescription is a simple two-party transaction between the pharmacist and the patient, and that a substituting pharmacist may avoid even a technical breach of contract by simply informing the patient that he is making a substitution. I would judge that the courts would be sympathetic toward a pharmacist who substituted without physician approval and who took a legal defense that seeks to make the patient responsible for the pharmacist's actions.

Reduced Prescription Prices?

Substitution advocates are appealing to the consumer, and particularly the consumer activist, that reduced prescription prices could be achieved by legalization of substitution. I have seen absolutely no evidence to verify this claim. To the contrary, experience in Alberta, Canada, where substitution is authorized, suggests

the opposite.

Many pharmacists understandably are concerned about the cost of maintaining multiple stocks of similar products. While there is no doubt that inventory costs rise when additional brands are stocked, it would be interesting to know how much they rise, and how many pharmacists actually stock *all* brands—of, say, ampicillin or tetracycline—or how long they keep "slow moving" products on their shelves before they are returned for credit. To ask that the industry eliminate multiple sources is to ask competitors to stop competing.

Drug Substitution—A License for the Unethical

Anti-substitution repeal would favor "corner cutting" pharmacists and manufacturers. For them, free substitution would be not a right, but a license. As an aftermath, it is quite likely that the confidence of both physicians and patients in the profession of Pharmacy would be eroded, as revelations about the unconscionable behavior of an undisciplined few were magnified in the press or in professional circles.

Summary

In short, what the American Pharmaceutical Association advo-

cates as a broad-spectrum panacea looks to us to be not only a minority view (advocacy of substitution is by no means a uniform policy in Pharmacy), but also an extraordinarily costly and ineffective remedy, whose side effects are odious. We believe (1) that an impressive majority of pharmacists prefer to work with Medicine and with industry, for the consumer, and for the general good, (2) that they seek the privilege to substitute when the patient might gain and when the patient's doctor agrees, and (3) that they seek to work for the resolution of genuine grievances openly and professionally.

President's Letter

Epilog

REPRESENTING THE MINNESOTA State Medical Association has been a wonderful experience. The frustrations, anger and fatigue that I spoke of in my first letter are still present. The problems of PSRO, unionism, national health insurance, continuing medical education, HMO's splintering of organized medicine have not been resolved, but all are more than counterbalanced by the people I have encountered.

One who cried when the magnolia blossoms froze during a late snow storm, some who laughed because it was good to have life again, staff who worked for you and me at Minnesota State Medical Association headquarters for many more than the stated forty hour week, I remember them all.

Colleagues who carried much of my work load, patients who understood and tolerated my absences, officers, councilors, committee members, editors, authors,* all devoting countless hours to medicine, and respondents to the President's Letter, all had something in common. They cared and they shared it.

My family who supported my efforts and our extended family, all of whom gathered in person or in spirit at a time of personal loss, they cared and they shared.

So this letter too is dedicated to people, all those whose lives touched mine in this past year. Many of them I don't know. We touched through print or by word of mouth and not in person, but they are there, they are real, and it was a wonder filled year.

George B. Martin

President
Minnesota State Medical Association

*[Many of those mentioned in this paragraph would appreciate the opportunity to respond to George Martin's epilog of thanks. I think I can speak for everyone who has worked with him in his great year as President of the Minnesota State Medical Association, who would like to tell him that he has earned our total admiration and respect. We too are part of his extended family. Ed.]

new SantylTM ointment (collagenase)

Indications: Santyl Ointment is indicated for debriding dermal ulcers and severely burned areas. In other types of necrotic skin lesions reports on the use of Santyl Ointment have been limited to clinical observations without controls.

Contraindications: Application is contraindicated in patients who have shown local or systemic hypersensitivity to Collagenase.

Precautions: The enzyme's optimal pH range is 7 to 8. Lower pH conditions have a definite adverse effect on the enzyme's activity, and appropriate precautions should be taken.

The enzymatic activity is also adversely affected by detergents and hexachlorophene and heavy metal ions such as mercury and silver which are used in some antiseptics. When it is suspected such materials have been used, the site should be carefully cleansed by repeated washings with normal saline before Santyl Ointment is applied. Soaks containing metal ions or acidic solutions such as Burow's solution should be avoided because of the metal ion and low pH. Cleansing materials such as hydrogen peroxide or Dakin's solution do not interfere with the activity of the enzyme. Debilitated patients should be closely monitored for systemic bacterial infections because of the theoretical possibility that debriding enzymes may increase the risk of bacteremia.

The ointment should be confined to the area of the lesion in order to avoid the risk of irritation or maceration of normal skin.

A slight erythema has been noted occasionally in the surrounding tissue particularly when the enzyme ointment was not confined to the lesion. This can be readily controlled by protecting the healthy skin with a material such as Lassar's paste.

Since the enzyme is a protein, sensitization may develop with prolonged use although none has been observed to date.

Adverse Reactions: Adverse reactions to Collagenase have not been noted when used as directed.

Dosage & Administration: Santyl Ointment should be applied once daily (or once every other day in the case of outpatients) in the following manner.

(1) Prior to application the lesions should be gently cleansed with a gauze pad saturated in normal saline, buffer (pH 7.0-7.5) or hydrogen peroxide to remove any film and digested material.

(2) Whenever infection is present, as evidenced by positive cultures, pus, inflammation or odor, it is desirable to use an appropriate topical antibacterial agent. Neomycin-Bacitracin-Polymyxin B (Neosporin) has been found compatible with Santyl Ointment. This antibiotic should be applied to the lesion in powder form or solution prior to the application of Santyl Ointment. Should the infection not respond, therapy with Santyl Ointment should be discontinued until remission of the infection.

(3) Santyl Ointment should be applied (using a wooden tongue depressor or spatula) directly to deep wounds, or, when dealing with shallow wounds, to a sterile gauze pad which is then applied to wound. The wound is covered with sterile gauze pad and secured with clear tape or Kling bandage.

(4) Crosshatching thick eschar with a #11 blade is helpful. It is also desirable to remove as much loosened detritus as can be done readily with forceps and scissors.

(5) All excess ointment should be removed each time dressing is changed.

(6) Use of the ointment should be terminated when sufficient debridement of necrotic tissue has taken place.

Overdose: Action of the enzyme may be stopped, should this be desired, by the application of Burow's solution U.S.P. (pH 3.6-4.4) to the lesion.

How Supplied: Santyl Ointment contains 250 units of Collagenase enzyme per gram of white petrolatum U.S.P. The potency assay of Collagenase is based on the digestion of undenatured collagen (from bovine Achilles tendon) at pH 7.2 and 37° C. for 24 hours. The number of peptides cleaved are measured by reaction with ninhydrin. Peptides released by a trypsin digestion control are subtracted. One net Collagenase unit will solubilize ninhydrin reactive material equivalent to 4 micromoles of Leucine.

Klippel-Feil Syndrome

EDWARD McELFRESH, M.D.* and ROBERT WINTER, M.D.†

THE KLIPPEL-FEIL SYNDROME is referred to as "brevicollis," "congenital cervical fusion" or "cervical assimilation" in the English literature. The Germans refer to it as *Kurtzhals* ("short-neck") while the French literature uses *le homme sans cou* ("the man without a neck").

Congenital cervical vertebral fusion was described in an Egyptian mummy from about 500 B.C.³⁸ There is also a report of the fusion of the cervical vertebrae and ribs in an ancient Paucarancha Indian of Peru.²⁵ Realdus Columbus, the successor to Vesalius at Padua, described in 1559, a case of occipito-atlantal fusion.⁶ Haller in 1743 described a case of congenital cervical fusion.¹⁸ Three years later, Morgagni presented two cases and mentioned others.²⁸ In 1850, Rokitsky described a 70-year-old tailor with a C2-7 fusion together with spinal deformities.³² There were numerous case reports between 1850 and 1912.

In 1912, Maurice Klippel and Andre Feil published a complete study of a case of a 46-year-old tailor who died of pneumonia and nephritis and described the signs of the syndrome. They reported the case in four publications that year.^{20,21,22,23}

Meisenbach reported the first American case in 1913.²⁷ In 1919, Feil reviewed the literature in a classic thesis.¹⁰ Bertolotti, a year later, described the triad of short neck, limitation of motion and low hairline.⁴ Dubreuil-Chambardel was the first to use the eponym of Klippel-Feil Syndrome.⁸

Embryogenesis and Etiology

The work of Strecker³⁹ shows that at 21 days of fetal life the first pair of occipital somites forms which then progresses distally. By the 27th day, cervical segments are being laid down and are finally completed by the 37th day. Soon after a

group of mesenchymal cells in each somite migrate toward the notochord, forming a sclerotome. The rostral half of each sclerotome fuses with the caudal portion of the adjacent sclerotome to form a vertebra.

If the lateral halves of the centrum do not fuse, anterior spina bifida or cleft vertebral body occurs and hemivertebrae are formed. Closure of the neural arches does not take place until much later. If the neural tube and skin have not separated, posterior meningocele or myelomeningocele is the result.

With chondrification of the vertebrae, the centra elongate at the expense of the intervertebral material and finally fuse or very nearly fuse in the region of the notochord to form an almost solid cartilaginous column during the eighth week. Normally this fusion is transitory, but if subsequent development of the disc fails to take place, or if presumptive disc tissue chondrifies and fuses with the vertebral body, the vertebrae remain solidly joined throughout life. Congenital vertebral fusion may be considered to date from the eighth week of intra-uterine life although Hadley¹⁷ claims that the defect occurs during the first month.

There have been various factors postulated as the cause of Klippel-Feil syndrome. Degenhardt and Kladetsky⁷ produced vertebral anomalies of the dorsal spine including "fusion" of vertebral bodies in 34% of rabbits whose mothers were subjected to decreased oxygen between the ninth and 11th days of gestation which corresponds to the 25th day of human gestation. Some people have suggested prenatal insult or disease such as radiation or infection, particularly in Turner's syndrome^{3,35} and the male phenotype of Turner's syndrome.^{19,26} Gray¹⁴ even postulated that all cases of Klippel-Feil syndrome are due to a chromosomal aberration similar to but not identical to Turner's syndrome. There is a definite trend for the Klippel-Feil syndrome to run in families, especially those with isolated fusion of two cervical vertebral bodies. Gardner¹¹ has tried to associate

*Fellow in Orthopaedic Surgery, Mayo Clinic, Rochester, Minnesota.

†Medical Director, Gillette Children's Hospital, St. Paul, Minnesota and Associate Professor, Department of Orthopaedic Surgery, University of Minnesota, Minneapolis.

From the Spine Service, Gillette Children's Hospital, St. Paul, Minnesota, J. H. Moe, Chief of Spine Service and Chief of Staff. This study supported by the Medical Education and Research Fund of Gillette Children's Hospital.

Klippel-Feil syndrome with myelomeningocele and diastematomyelia as another form of the neural tube failing to close.

None of the theories completely explains the failure of vertebral segmentation.

Incidence, Classification and Material

The incidence of Klippel-Feil syndrome is reported to vary from 1:42,000 births²⁴ to 3:700 births.³⁶ The literature varies as to sex difference but most authorities feel there is equal sex involvement. Gray's review of the world literature showed that females tended to be seen at an earlier age and had more severe involvement. In the Gillette Hospital series there were eighteen males and twenty-eight females.

In his 1919 thesis, Feil classified Klippel-Feil syndrome in three types which we have chosen to follow in reviewing our cases. *Type I* is the classic type of cervical and upper thoracic vertebral block fusion and other vertebral defects. *Type II* is an isolated fusion of two cervical vertebrae. This is the most common type but usually causes no symptoms and is detected usually on a routine roentgenogram. *Type III* is either Type I or II associated with either lower thoracic or lumbar vertebral involvement. The Type III has been further divided into subgroups I or II depending upon involvement of the cervical spine. Gundersen and associates¹⁵ have shown that the most common type of isolated cervical fusion, C2-3, is an autosomal dominant lesion while C5-6 fusion is autosomal recessive.

Of the 46 cases in our series, 25 were Type I while there was only one Type II fusion. There were 20 Type III lesions with 16 showing a Type I cervical lesion and four showing a Type II cervical fusion. Isolated Type II lesions are unlikely to be seen at a hospital for crippled children since no deformities or disability is produced.

Pregnancy and Delivery

There were 31 normal pregnancies and deliveries in the Gillette series. Two births were premature; nine had prolonged difficult labor. Three of these were instrument deliveries and one birth was a breech delivery. There was one Cesarean section, and two babies born with the cord wrapped around the neck. The birth histories of two were unknown.

Associated problems included an appendectomy in a mother during the seventh week of pregnancy with a number of Xrays being performed at the

time. Two mothers had influenza during the first trimester of pregnancy. One patient had a twin stillborn with a cranial myelomeningocele. This could be used in support of Gardner's theory that Klippel-Feil syndrome is part of the spectrum of the neural tube failing to close.

Diagnosis

The *diagnostic triad* is: (a) a short-neck, (b) low hairline and (c) limitation of motion. In the literature, slightly over 50% of patients exhibit the triad. In the Gillette series, 18 patients had the triad while 16 had a short-neck and motion limitation but not a low hairline. Three patients had two characteristics but had no limitation of motion while one patient did not have a short-neck. Seven patients had either a short neck or limitation of motion only. One patient exhibited none of the characteristics of the triad.

The diagnosis of Klippel-Feil syndrome depends upon Xray of the whole spine. A-P, lateral and oblique views are needed. The A-P view is often obstructed by the mandible or the low occiput. Also helpful may be an open-mouth view and tomograms.

In addition to the vertebral body fusion, the Xrays should be examined for spina bifida which Gjorup and Gjorup¹³ say is the most common lesion besides the block fusion. Cleft vertebral bodies, hemivertebrae, widened neural canal, atlanto-occipital fusion, deformed dens, platybasia, and the occiput riding on the posterior upper thorax are other defects that may appear.

Thirty-eight of the 46 patients had a spina bifida and 20 patients exhibited a cleft in a vertebral body. All 20 of the patients with a cleft vertebral body had a spina bifida although not always at the same level. Fourteen had cervical hemivertebrae and there were 27 with thoracic hemivertebrae. Six of these had hemivertebrae in both the cervical and thoracic regions.

A deformed odontoid was found in 18 (two of these were absence of the dens). An atlanto-occipital fusion was found in 22 patients. In 14 instances both atlanto-occipital fusion and deformed dens were found to be coexistent. Platybasia was found in 11 cases.

Associated Deformities

Sprengel's deformity was found in 15 patients. There were three bilateral cases, three involving the right side, and nine involving the left side. The literature¹⁴ reports about a 25% incidence of

prengel's deformity with Klippel-Feil syndrome. There were three instances of omovertebral bones. Operations performed included three Schrock procedures, three Woodward procedures, two Green procedures and plastic repair of the scapulae in a bilateral case.

Assymetry of the head was found 15 times and facial assymetry 20 times. In nine instances, both characteristics were present together. Platycephaly and brachycephaly were the most common cranial deformities.

There was one patient with hydrocephalus and the possible diagnosis of iniencephaly. Gilmour¹² felt that Klippel-Feil syndrome is a mild variation of iniencephaly.

Eye abnormalities included five patients with squints, four with ptosis, two with third nerve palsy, three with sixth nerve palsy, and one with nystagmus.

Seven patients had ear abnormalities, usually being low set ears although one patient had preauricular tag. A hearing deficit was found in seven patients, usually a conductive hearing loss.

Cleft palate was found in six patients only one of which had a cleft lip. Defects associated with a cleft lip are usually inherited while those with only a cleft palate are developmental in origin.³³ There was one patient with a cleft uvula, a variant of cleft palate. There were eight instances of a high arched palate.

Rib abnormalities included eleven instances of fused ribs, ten with absent rib and nine cervical ribs. Chest defects included three cases of pectus excavatum, four cases of pectus carinatum, and one case with a Harrison groove.

Thirteen patients exhibited a torticollis either of a muscular or bony origin. Pterygium colli or webbed neck was found in eleven instances. Additional pterygia were found in four cases and were as follows:

1. Axillary
2. Axillary, elbows, hips, knees, and first web spaces
3. Axillary, elbows, and right knee
4. Axillary, hands, and knees

Chromosomal studies done on two patients were within normal limits while another is being studied as a possible male phenotype of Turner's syndrome.

Scoliosis greater than 20 degrees was found in 29 of the 46 patients. Of the Type I cases, five were greater than 40° and were usually associated with hemivertebrae. Sixteen of the Type III cases

were greater than 40°. The greatest curve was found in a girl with thoracic unsegmented bars on opposite sides with a normal vertebra between. She went from 92° when first seen to 135° nine years later.

Neurological lesions included six cases of arm weakness and four cases of hyperreflexia of the lower extremities. The only recorded case of mirror movements associated with Klippel-Feil syndrome was seen in a girl at Gillette Hospital in 1924 which is six years before the first report in the literature by Bauman.² This girl was two years old before she could sit by herself or crawl. Mirror movements have recently become the focus of neurological study in Klippel-Feil syndrome.^{1,16} There were isolated instances of a present Babinski and clonus. One patient exhibited symbiotic autism. Cervical root lesions present since birth were found in two patients, one of which exhibited a Horner's syndrome, absent sweating of half the body, and winging of the scapula. Serious neurological deficits usually do not appear before the twenties and, therefore, were not prevalent in this series. Patients with Klippel-Feil syndrome are reported to have an increased susceptibility to cervical fractures and fracture-dislocations with minimal trauma.³⁷

Cardiac abnormalities in this series included a case of surgically repaired patent ductus arteriosus, two cases of dextrocardia, and two systolic murmurs which were never properly evaluated. Cardiac abnormalities were emphasized by Nora and associates.³⁰ Intestinal problems included an isolated tracheo-esophageal fistula, situs inversus, and bowel obstruction requiring surgical intervention.

Intravenous pyelograms were performed 14 times and were abnormal in six including two patients with agenesis of a kidney, two ectopic kidneys and two crossed renal ectopia. Recently two other cases of renal agenesis have been reported.³¹

Of the 18 males, the status of the genitalia was recorded in 16. There were six cases of undescended testes. Two of the females had been shown to have an absent or vestigial vagina and uterus.

Defects of the hands included two cases of radial club hands with absent thumbs, a hypoplastic thumb, a patient with familial clinodactyly of the fifth fingers, and vestigial nubbins with the patient with probable male Turner's syndrome.

Two patients developed tumors, a chondrosarcoma requiring hip disarticulation, and a giant

cell tumor of a tendon sheath of the extensor tendon of the left index finger.

Treatment

The treatment of scoliosis of the Type I lesions included seven patients treated with Milwaukee bracing. The three patients with a curvature less than 20 degrees who were treated with a Milwaukee brace were started before the age of one year. There were three fusions performed in the Type I lesion and were basically of the upper thoracic area. The history of one of these patients does not make note as to the level of fusion.

The Type III (I) lesion was treated in two patients with a Milwaukee brace. Fusions were performed eight times and included the cervical spine two times. The Type III (II) lesions were fused in the thoracic and lumbar spine in three of the four cases with the other patient being treated with a Milwaukee brace since his family refused spinal fusion.

Most reports in the literature indicate conservative treatment in Klippel-Feil syndrome is of no value and only serves to increase the misery of life already made unpleasant by the deformity. The Milwaukee brace is useful for thoracic scoliosis. A Schanz collar has been recommended by Russe.³⁴ Physiotherapy is of no value.

Surgical procedures described in the literature^{5,14,29,40} for the Klippel-Feil syndrome include suboccipital craniotomy and cervical laminectomy, cervical laminectomy, spinal fusion, removal of cervical and upper three thoracic ribs with trimming of the trapezius muscle, resection of the outer portion of the trapezius muscle, and plastic repair of pterygium colli.

Surgery in Klippel-Feil syndrome is of value to improve function, appearance and to limit progressive neurologic complaints.

Contraindications to surgery are a poor surgical risk generally, an asymptomatic person who has adjusted reasonably well, and a patient with a surgically incorrectable neural anomaly in addition to a bony defect.

Two patients have had operative procedures other than spinal fusion performed for Klippel-Feil syndrome at Gillette Hospital. One patient had plastic surgery repair of her pterygium colli following correction of her bilateral Sprengel's deformity. Cosmetically she obtained an excellent result and was quite pleased with the improvement of her physical appearance.

The other patient was a twelve year old girl with a markedly shortened neck with an extreme webbing. The hairline extended down onto the thorax. The shoulders were elevated and rotated forward about 50 degrees with shortened malformed clavicles. She could flex and extend her neck only 15 degrees with no rotation present. She also had a bilateral sixth nerve palsy and axillary webbing. Xrays showed congenital absence of the odontoid, platybasia, cervical fusion, cervical ribs, and the occiput almost reaching the thoracic spine. A Milwaukee brace with outriggers was used in an attempt to hold the shoulders in good position but was of no real help. The surgical procedure included a v-shaped incision over the shoulder with a medial base. The trapezius muscle was freed from the clavicle, acromion, and scapular spine. The clavicle was dissected free subperiosteally and the outer two-thirds resected. The acromion was also excised. The subcutaneous tissue and skin were closed in a y-plasty, removing the webbed appearance of the skin of the neck. Later the same procedure was performed on the opposite side. Postoperatively she had essentially the same flexion-extension of the neck but had obtained a small amount of rotary motion. The shoulders were still held in a forward position but not as much as preoperatively. She was again placed in a Milwaukee brace with outriggers but a few months later she refused to wear it. Follow-up two years later showed prominence of the medial, non-resected portions of the clavicles which were excised. Follow-up four years after the original surgery showed excellent improvement of the levels of the shoulders, but increased forward rotation of the scapula. An interscapular fascial sling operation was refused.

Discussion

Does the Klippel-Feil Syndrome deserve to stand alone as a specific entity? The tendency to lump together patients who have as their sole item of common interest a congenital failure of segmentation of cervical vertebrae stretches the term "syndrome." The original description of a patient with a short neck, low hairline, decreased cervical motion and failure of segmentation of cervical vertebrae does indeed constitute a useful grouping of symptoms and a recognizable entity.

Type II lesions, the isolated "fusion" of two vertebrae with no deformity, no symptoms, and essentially no pathology should not be included

in the Klippel-Feil Syndrome. Type III lesions with vertebral anomalies in other areas of the spine and coincidental cervical lesions is intermediate in justification for inclusion in the Klippel-Feil. Congenital failure of segmentation is just as common in other areas of the spine and has not earned the eponym.

This review highlights the great frequency of associated anomalies, from skeletal, such as congenital absent radius, to cardiac, and genitourinary. The physician confronted with a patient with the Klippel-Feil syndrome is obligated to investigate other organ systems, especially the genitourinary.

A recent review at Gillette Hospital of routine intravenous pyelography in 88 patients with congenital anomalies of the spine (myelomeningocele excluded) has revealed a 28% incidence of anomalous genitourinary tracts, several having obstructive uropathy.

Audiologic deficits might easily be missed unless one realizes the high incidence of hearing loss in the Klippel-Feil Syndrome. It is this "triggering" of interest in other organ systems that is a prime dividend of recognizing this syndrome.

Summary

Forty-six cases of the Klippel-Feil Syndrome, none previously reported, were reviewed at the Gillette Children's Hospital, St. Paul, Minnesota. Both the clinical and radiologic features were reviewed in detail. The large number of associated anomalies is of particular interest. Sprengel's deformity was noted in 15, cranial asymmetry in 15, ocular abnormalities in 15, ear deformity in seven, hearing deficit in seven, cleft palate in six, and cleft lip in one.

Eleven had fusion of ribs, 10 had absent ribs, nine had cervical ribs, eight had chest deformity, 13 had torticollis, 11 had webbed neck, 29 had scoliosis greater than 20 degrees, 11 had neurologic deficits, five had congenital cardiac defects, six had abnormal intravenous pyelograms, six had undescended testes, and two had absence of the vagina and uterus.

Surgical treatment of the cervical deformity was seldom attempted but an occasional case may benefit from correction of web neck, correction of elevation of the scapulae, and correction and fusion of scoliosis deformity.

Femoral Neck Fractures

Analysis of Hip Prosthetic Replacements

Hennepin County General Hospital

RICHARD H. MOORE, M.D.,* ROBERT F. PREMER, M.D.† and RAMON B. GUSTILO, M.D.‡

AVIABLE, UNITED FEMORAL head is the ideal result following a fracture of the femoral neck, but this often is not achieved. Prosthetic replacement, rather than internal fixation, is indicated in selected patients. The aim of the operation is to produce a stable, relatively painless hip, suitable for early weight bearing that will serve the patient for the remainder of his life. The selection of the proper patients for treatment with a prosthesis is still a problem and remains controversial. The relative indications often given for the use of a femoral head prosthesis in patients with normal acetabula are:

1. Irreducible fractures
2. Fracture dislocations
3. Elderly patients physiologically 70 years or older whose activity is already significantly limited by age or disease
4. Patients who could not reasonably be expected to tolerate a second operation
5. Parkinson's disease
6. Pathologic fracture
7. Fractures that have "fallen apart" i.e. following unsuccessful nailing, nail penetration, non-unions, avascular necrosis, etc.
8. Primary idiopathic avascular necrosis including kidney transplant patients

For the last twenty years, after the initial decision was made for primary or secondary prosthetic replacement, intermedullary prosthesis such as the Austin Moore, Minneapolis or Thompson Prosthesis have been the most widely accepted. Recently, cementing in a femoral prosthesis or doing a total hip replacement has been advocated as another alternative. The latter is a more extensive procedure in that both the femoral and acetabular components are implanted. Is the more extensive procedure justified? At this time there is no data with long term follow-up on patients treated for

femoral neck fractures with total hip arthroplasty.

It has been our impression that prosthetic head replacement for the treatment of femoral neck fractures has been very satisfactory. In an attempt to corroborate this we reviewed the literature and our cases at Hennepin County General Hospital from 1962 to 1971.

The Operating Room Log was reviewed and 184 prosthetic replacements were found in this ten year period. The charts of only 172 hips in 166 patients could be located (Table 1). There were six patients with bilateral prostheses. There were 153 Austin Moore's (Figure 2) and 19 Minneapolis prosthesis (Figure 2) in 122 females and 50

Fig. 1—A displaced femoral neck fracture in a 78-year-old woman.

males. The average age of the entire groups was 75.6 years. Of these, there were 144 prostheses for acute fractures (103 females and 41 males) with an average age of 78 years (Table 2). The average hospital stay was 29 days and the time from fracture to surgery was 3.7 days.

TABLE 1	
Femoral Head Prosthetic Replacement Reviewed at Hennepin County General Hospital between 1962 and 1971	
172 Hips in 166 Patients	
122 Females

TABLE 2	
144 Prostheses in Acute Fractures	
103 Females	41 Males
Average Age	78 Years
Average Hospital Stay	29 Days
Fracture to Surgery	3.7 Days

There were 28 prostheses as secondary treatment for femoral neck fractures (i.e. following non-union, avascular necrosis, penetrated nails, etc.) (Table 3). In this group there were 19 females and nine males with an average age of 63.2 years and an average of 16 months from fracture to prosthesis. Their average hospital stay was 39.6 days.

TABLE 3	
28 Secondary Prostheses	
19 Females	9 Males
Average Age	63.2 Years
Average Hospital Stay	39.6 Days
Fracture to Surgery	16 Months

We were able to examine 41 hips in 36 patients with an average follow-up of 41.6 months. Adequate information was obtained on another twelve patients by telephone contact. In 18 other patients, there was sufficient information from the old charts to be included with an average follow-up of 12.5 months. There were 66 patients known to have died as of July, 1972.

Indications for a prosthesis has varied somewhat through the years, but in general, prostheses have been used in patients who were 75 years old or older, or had irreducible fractures and in patients where there was a delay of more than 24 hours between the time of fracture and when they went to surgery. In many of our patients, the initial condition on admission was such that they were considered too great a surgical risk, so their surgery was postponed until they were medically stable. In acute fractures, the delay between fracture and surgery was almost four days (3.7).

Complications

There were 22 [in hospital] deaths (12.8%) which were all in the acute fracture group (Table 4). In addition, there were another 14 patients known to have died within six months of surgery or a total of 36 patients (20.3%) in the entire series. Their average age was 81 years. Of those deaths directly related to surgery, seven died of complication from wound infection, seven from pneumonia, four from pulmonary emboli, two from myocardial infarcts, one from a stroke and one from serum hepatitis. There were 36 inpatient non-fatal complications (20.9%) and nine late complications. In the entire series there were 16 infections or 9%. Ten of these were deep infections (5.2%). Seven of the 10 patients with deep infections died during their hospitalization.

Non-fatal complication rate 20.9%.

There were nine late complications (Table 6). There were four patients who had fractures below their prosthesis from two to five years after prosthetic placement. There were four additional prosthesis removed, one for late dislocation and only three for painful prosthesis. Two of these patients received their prosthesis for avascular necro-

sis following fracture. There was one case of painful protrusion of the prosthesis into the acetabulum.

Results and Discussion

In assessing the results we modified the Merle D'Aubigne method⁸ in grading the parameters of pain, motion, and function (Table 7).

TABLE 7

Analysis of Prosthesis

I. Pain

Poor —	0—Intense & Permanent
	1—Severe Pain at Rest
	2—Severe Pain with Ambulation; Prevents Activity
Fair —	3—Tolerable Pain with Limited Activity
	4—Mild with Walking—None at Rest
Good —	5—Mild & Unconstant—No Limitation of Activity
	6—No Pain

II. Range of Motion

Poor —	0—Ankylosis with Malposition
	1—No Movement with None or Slight Deformity
	2—Flex Less than 40 Degrees
Fair —	3—Flex 40 to 60 Degrees
	4—Flex 60 to 80 Degrees; can Reach Foot
	5—Flex 80 to 90 Degrees; Abduction 15
Good —	6—Flex Greater than 90 Degrees; Abduction 30

III. Function

Poor —	0—Cannot Walk
	1—Can Walk Only with the Aid of Crutches or Walker
	2—Can Walk Only with the Aid of a Cane
Fair —	3—Without Cane for Less than One Hour, Hard to Walk without Cane
	4—Extended Walk with Cane; Short Walks without Cane & with Limp
Good —	5—Slight Limp with Cane
	6—Normal

In the acute fracture group with an average follow-up of 40 months, 80% had little or no pain, 87% had a good range of motion and 25% were able to walk well without a cane.

In the secondary prosthesis group that had an average follow-up of 46 months; 84% had little or no pain, 87% had a good range of motion and 25% were able to walk without a cane. Overall, 81.5% were termed "good" in grading for pain, 77.5% "good" for range of motion and 25% "good" for *function* or walking ability (Table 10).

The results are somewhat misleading in that we find only 25% had what were defined as good *functional* results. In assessing the results we must keep in mind that the average age was nearly 80 at the time of follow-up. We must also keep in mind what we had hoped to accomplish by this procedure, i.e. a relatively painless, stable hip. Considering this then, well over 80% had a satisfactory results. An 80-year-old patient who has a painless hip, an adequate range of motion but requires a walker for balance should be considered a satisfactory result even though in using our system he would fit the "poor" group under *function*.

In 1964, Hinchey and Day⁵ reported their series of 294 fresh fractures treated with femoral head prosthesis. They found that overall, 84% of these had satisfactory results with a one to eight year follow-up and those that were followed for over four years had a 90% satisfactory result. Furthermore, they did not find any tendency for deterioration of the results between four and eight years. Anderson¹ (1964) reported 84% good results in 33 fresh (acute) fractures which were followed an average of 40.5 months. Lunceford⁶ (1965) had good or excellent results in 89% of 37 patients. Hinchey and Day⁵ reported in their 37 patients that had *poor* results, 29 of these poor

results could be attributed to pre-existing medical diseases and only in nine due to hip pain.

Similarly, in our patients, the poor functional results were due almost invariably to medical problems and senility and not to hip pain. It should be noted, that a majority of our patients that we could locate and were available for examination, were patients in nursing homes. This may be a factor in biasing our results toward poorer function. The one patient who was seen in clinic and had significant pain, also had had a stroke and could not ambulate because of this and did not wish any further treatment. Our mortality rate of 12.8% in the immediate postoperative period and wound infection rate of 9% is higher than we would expect with hip pinning. For the last few years, we have treated intracapsular fractures as semi-emergencies and have tried to fix them with a Massie nail within the first 24 hours, regardless of the patient's age. The Austin Moore prosthesis was used for acute fractures that cannot be adequately reduced or that are more than 48 hours old and in patients with Parkinson's disease.

Whenever possible we use the Austin Moore prosthesis with the long stem (Figures 2 and 4). We feel that this newer design gives more stability. We approach the hip using either Moore's low posterior incision (Southern Exposure)⁹ or Marcy's⁷ modification of the Gibson posterior lateral incision. We have noted that a good appearance of the prosthesis on Xray, generally means a good result (Figure 3). The prosthesis should be well seated on the medial cortex. The femoral

TABLE 8

neck should be cut to the proper length. The top of the prosthetic head should not be more than $\frac{1}{2}$ " above the greater trochanter. The prosthetic head must accurately and concentrically fit the acetabulum.

Conclusions

Over 80% of the patients achieved a satisfactory result using prosthetic femoral head replacements for femoral neck fractures. This figure is comparable to other reports in the literature.^{1,5,6,9} We feel that the results of treatment with the Austin Moore prosthesis are satisfactory and do *not* justify the use of total hip replacement or even to cementing in a femoral prosthesis in a routine acute femoral neck fracture when the acetabulum is normal. We can only speculate that since the total hip replacement is a more extensive (and expensive) surgical procedure, that the complication rate would likely increase in this type of patient and that the long term results would not be significantly improved.

in Humeral Shaft Fractures

THOMAS H. COMFORT, M.D.*

THIS PAPER REPORTS a new treatment of humeral shaft fractures being used at Saint Paul-Ramsey Hospital in the unconscious patient or the patient with multiple-injuries. The sugartong splint held with adherent foam to the arm, and used as a long splint to control the angulation, with special regard to the angulation apex lateral at the fracture site, is an efficient and relatively simple method of treatment which has given good results. Half of the patients had an injury to the chest, abdomen, head or other extremity which required bedrest. Traction, while satisfactory for maintaining the alignment of humeral shaft fractures, undesirably restricts positioning and remobilizing injured patients. Traction requires constant attention in patients who are unconscious, irrational or overactive. Even co-operative patients develop distraction with this treatment. A variant is to apply a hanging cast with traction while the patient is lying down. This allows the patient to sit up intermittently or to rest flat in bed. The arm must be repositioned at each move.

The standard treatment of humeral shaft fractures in the 1930's was a spica type cast, or a humeral abduction frame. Both of these are difficult to apply, often requiring general anesthesia, and difficult to maintain in position, with immobilization of the joint above and below the fracture. Excessive motion of the cast on the body is transmitted to the fracture site causing both an increase in healing time (average: over ten weeks) and frequent non union. The muscles of the shoulder, elbow and hand could not be easily exercised, and stiffness was a problem in older patients. Boehler suggested a smaller spica cast which held the arm abducted slightly, and allowed some motion at the elbow, hand and wrist, and reported more satisfactory union rates.

Caldwell advocated the hanging cast treatment in 1933, and reported a series of fractures treated in 1940 with a sharp decrease in the incidence of non union. He found that the hanging cast was preferable for almost all types of humeral shaft fractures, providing that it was a light cast, that the arm was held dependent, that the elbow was flexed 90°, that the sling was properly fixed at the wrist, that weekly roentgenograms were taken to correct angulation, that active exercises of the muscles of the shoulder, fingers and thumb were continued, and that traction was continued on the cast if the patient was in bed.

Watson-Jones and Boehler both advocated a plaster sugartong type splint going down the inner aspect of the arm around the elbow and up the lateral aspect of the arm. Both commented, however, that in shaft fractures, there was a tendency toward angulation apex lateral, and it was necessary to use a padding or abduction splint in order to hold the distal fragment out from the body, and the collar and cuff suspension at the wrist to allow slight traction from the unsupported elbow. Here again a very close supervision of the patient is required in order to accurately maintain the distal fragment in relationship to the upper fragment of the humerus avoiding distraction, excessive motion, or angulation.

The usual problem in humeral shaft fractures is that the upper fragment, if it includes the attachment of the deltoid muscle, tends to be held in slight abduction because the deltoid muscle is far stronger than the muscles at the shoulder joint which tend to adduct the humerus, while the lower segment tends to adopt a position close to the support of the body. If a splint could be made long enough so that three points of pressure could be developed, one pressing the lower fragment out laterally from the body, a higher force pressing the upper fragment in medially, and the torque of these correcting forces resisted by continuing the

splint over the shoulder area, then alignment could be controlled by the splint alone. If this apparatus can be made light enough so the distracting forces are not developed as in the shoulder spica cast, it would be reasonable to assume that union rate equivalent to that of the hanging cast could be realized. The problem is how to comfortably apply a splint, incorporating the deltoid area.

We have attempted to achieve this goal by using an adherent type of padding under the plaster layer. This is a polyurethane foam which has an adherent surface yet it is not irritating to the skin. The adhesive is distributed in a particulate form so that a solid occlusive film is not developed. The foam is an open pore structure allowing air and moisture to pass through it. It can be obtained in 3/16th or 5/8th inch thicknesses. Usually, we use a single thickness of 3/16th inch on the inner and outer aspect of the arm, and a double thickness over the bony prominences at the elbow. A plaster splint of ten thicknesses is applied over the foam and fastened in place with a temporarily applied elastic shoulder spica bandage. This causes the plaster to penetrate the pores of the foam sufficiently so that it is adherent to the foam. While the plaster is setting, the arm must be carefully molded creating the pressure point on the lateral aspect of the upper fragment, at the same time holding the distal fragment in an abducted position. The properly applied splint has a shallow U-shaped outer contour in its distal two-thirds, and extends over the upper aspect of the shoulder. Fractures of the distal third of the humerus need not have the extension over the shoulder. After the plaster has set, the elastic wrapping is replaced. With the second wrapping, the tension can be reduced and the wrapping need not pass across the shoulder under the opposite arm. The splint will allow slight motions of the shoulder which should be encouraged during the healing phase; a collar and cuff controls motion of the elbow, usually held at 90° of flexion. In fractures of the distal third of the humerus, it is occasionally necessary to add a posterior splint to control the anterior-posterior relationships at the fracture site. If the patient is ambulatory and co-operative, a hanging cast may be preferable to sugartong splints in distal fracture, and some patients are transferred for this reason into a hanging cast after initial splinting of the fracture with a

sugartong cast. In general, we found sugartong treatment alone was satisfactory in 30 of 38 patients. In eight patients a hanging cast, plates, Velpeau bandage, traction and posterior splints were also used.

The fractures were transverse in 19 patients, spiral oblique in 13, comminuted in four and segmental in two. Of the patients, 21 were males, 13 had right sided fractures, and 19 of the 38 had associated injuries.

We found, then, that the hanging cast was not indicated in a large number of these 38 patients for the following reasons: Bedrest was necessary in 19. Nineteen had transverse fractures, three were unconscious, two had acromioclavicular separation of clavicular fractures. Two had brachial plexus injuries that would allow subluxation of the humeral head with traction.

Twenty-eight of thirty patients were healed with less than 15° of angulation. The average healing time was 7.6 weeks and varied from four to 12 weeks except for one actual and one potential non-union. One was a 66-year-old patient with a comminuted fracture who probably would have healed with either a sugartong splint or a hanging cast. She had a fracture of the patella, and of the mandible which demanded bed rest, and therefore was more easily treated with a sugartong splint. The splint was removed eight weeks after the fracture before firm consolidation had occurred in this unusually comminuted injury. The patient was a vigorous person who tended to wave her arm about testing to see if it was working when seen one month after the removal of the sugartong splint. Accordingly, it was elected to apply a long plate and bone grafting, rather than to continue attempts at closed treatment. The other patient was a 27-year-old male who was tried initially in a sugartong splint, and poor alignment was seen. A re-application of the splint was not attempted. The patient was transferred to a hanging cast, and again had poor alignment with distraction. The initial fracture had been an open wound from a high speed automobile injury. It was considered that the distraction was due to extensive soft tissue damage at the fracture site, and that even if the fragments could be held in close proximity, that delayed union was likely. Accordingly, he was admitted to the hospital 17 days after the injury for internal fixation of the fracture site.

Recurrent Hemangioma of the Hand

Associated with A Digital Arteriovenous Malformation

JAMES H. HOUSE, M.D., M.S.*

HEMANGIOMATA ARE FAIRLY common neoplasms but only occasionally occur in the hand. Stack in a study of 300 consecutive tumors of the hand noted only six hemangiomas.⁴ This tumor may be present at birth and regress spontaneously but occasionally will continue to enlarge so as to interfere with hand function. In rare cases a hemangioma may become pulsatile by acquiring communications with an artery and may assume the characteristics of an arteriovenous aneurysm extending over large areas.³

The capillary hemangioma involving the skin needs little attention, but can be treated with coagulation, freezing, radiation or surgical excision if location and size warrant treatment.¹ Hemangiomas may develop deep ramifications into the soft tissues of the hand and have been observed to invade tendons and bones resulting in functional impairment and necessitating radical excision to avoid recurrence.⁵

Case Report

A patient was noted to have a congenital hemangioma on the ulnar aspect of the right middle finger at the time of her birth. At the age of 15 years surgical excision of the mass was attempted at another hospital. Radiation therapy was administered approximately six months later when recurrence was noted. During the next two years the patient noted a progressive increase in size of the lesion and became aware of pulsation present in the finger and in the veins on the dorsum of her hand. When referred for further evaluation, the involved middle finger was noted to be one centimeter longer than the middle finger of the left hand and was 1.2 centimeters greater in circumference (Figure 1). There was a cutaneous birthmark measuring approximately eight by 30 millimeters on the ulnar aspect of the finger with a well-healed mid-lateral scar (Figure 2). The mass was soft and pulsatile and could be substantially decreased in volume by sustained compression. Pulsations were visible in the dorsal veins and a bruit could be heard over the mass with a stethoscope. The digital Allen test demonstrated that the primary arterial supply was by way of

Figure 1

Figure 2

*Associate Professor, Department of Orthopedic Surgery, University of Minnesota, Minneapolis.

Figure 3

Figure 4

the ulnar digital artery though the lesion did fill from the radial digital artery as well.

A transfemoral brachial arteriogram was performed which demonstrated an extremely active arterial blood flow to the right middle finger (Figure 3). There was very early dorsal venous filling through a large arteriovenous anastomosis in the lesion with relatively delayed filling of the smaller arteries to the remaining fingers.

Operation

An enbloc excision of the lesion was undertaken removing an ellipse of skin with the underlying hemangioma, ulnar digital artery and two large communicating dorsal digital veins (Figure 4). The volar digital nerve was carefully dissected free and preserved. Multiple communicating arteries and veins from the radial side of the finger were controlled by individual ligation and cautery. The specimen measured two by four by seven-tenths centimeters and was histologically a hemangioma with many large thick-walled vessels consistent with the clinically observed arteriovenous communication.

Discussion

The large arteriovenous communication demonstrated in this lesion may represent a progressive development of the lesion but probably is a result of the previous subtotal resection with the development of an arteriovenous fistula as the lesion recurred. The increase in skeletal length resulting from the increased blood flow that had occurred during her active growing years was not deemed to be sufficient to warrant surgical treatment. Normal sensory function was maintained in the digital nerve distribution and the surgical excision substantially reduced the circumference of the finger. The patient was pleased with the cosmetic and functional results of surgery.

Summary

Vascular neoplasms of the hand can occasionally enlarge or invade structures of the hand resulting in functional impairment. Angiography is a useful tool in evaluating the extent of the lesion and facilitates surgical excision by demonstrating the primary vessels involved in arterial supply and venous drainage.

Diabetic Foot Problems

Pathogenesis

WILLIAM J. KANE, M.D., Ph.D.*

"In Britain, at least, more hospital beds are occupied by patients with bad feet than all the other complications of diabetes put together."—Malins¹

GANGRENE OF THE FOOT is 50 to 70 times more common in diabetics over 40 than in the age-equivalent, nondiabetic population.² Between a third and a half of the amputations performed in this country are due to diabetic lesions of the lower extremities. The factors which lead to diabetic gangrene are multiple. Fortunately some of them can be corrected if they are recognized and managed promptly.

But, if these factors are unchecked, gangrene may be inevitable.

Ischemia is the major factor, but others are: neuropathy, reduced resistance to infection, and altered skin pressure relationships. There are other factors which are incompletely understood—such as diminished capillary diffusion and capillary bed sludging.

Ischemia is the insufficient flow of blood to tissue which in turn leads to changes in the function and morphology. The normal blood flow to muscle under resting conditions in man is five ml/min—100 gm of tissue, to cortical bone -1, to skin -9, and to nerve -6.³ Venous occlusion plethysmography shows no difference in resting flow values between diabetics and nondiabetics, but it's obvious that even ordinary functions such as walking can cause a marked increase in the metabolic requirements of tissues. The human basal metabolic rate is about 18 cal/min-Kg. Walking nearly doubles that rate to 33 cal/min-Kg. Most of that increased energy expenditure is in the lower extremities and muscle blood flow values in the leg become five to ten times more than the resting level. It is at this point that lower extremity tissue oxygen needs exceed their supply and irreversible changes occur. Inflammation and

infection inflict the same increased (excessive) demands on the vascular network.

Causes of Vascular Insufficiency

What are the causes of this vascular insufficiency? Are the lesions of diabetes the same as those of arteriosclerosis? One way to visualize the vascular pathologic changes of diabetes is to recognize that diabetics can have two types of vascular disease in their extremities. They can have the typical atheromatous disease which is characterized by a diminishing severity of the vascular lesions as the arteries diminish in size. The iliac and femoral arteries show the most advanced stages, the popliteal and tibial less, and the dorsalis pedis and digital vessels only very little sclerosis. There is splitting and fraying of the internal elastic membrane, mucopolysaccharides are deposited, lipids accumulate, plaques are formed, and the media calcifies. Microscopically, the arteriosclerotic lesion in the diabetic is indistinguishable in major arteries from the lesion in the nondiabetic. Although it seems the lesion develops in more diabetics whose disease has persisted for ten years than in the age-adjusted nondiabetics.^{5,6} In the diabetic population there is no sex difference at any age as contrasted with the male predominance at earlier ages in the general population.¹

The treatment of peripheral arterial disease in diabetics is no different than in nondiabetics, once the roles of neuropathy and infection have been determined to be playing in producing "diabetic gangrene." Diabetes itself is not a contraindication to arterial surgery, either endarterectomy or by-pass graft, no matter how long the patient has been diabetic or how severe the diabetes is.

The second obliterative vascular lesion in dia-

*Professor and Chairman, Department of Orthopaedic Surgery, Northwestern University Medical School, 303 E. Chicago Avenue, Chicago, Illinois.

betics is in some dispute and is called "diabetic microangiopathy." Some investigators have claimed that it is a distinct entity affecting mainly the capillaries but sometimes extending into the arterioles and venules in a patchy distribution.⁷ Characteristically, there is a glycoprotein precipitated in the capillary basement membrane and a proliferation of the endothelial cells. The current evidence that microangiopathy precedes the appearance of carbohydrate dysfunction is as one author states, "so persuasive that redefinition of diabetes has been proposed to include microangiopathy as an integral component of the disease, if not its primary expression,"⁸ and that the vascular disease may be "genetically determined, antedating, and independent of, the overt metabolic disturbances."⁹ It may be "that the disease of the small pancreatic vessels precedes and is responsible for interference with islet cell function."^{10,11} These changes have been well documented for the tissues of the diabetic leg.^{7,12}

Later studies have shown basement membrane thickening and endothelial cell enlargement and proliferation in other areas such as the dermis of the finger¹³ and the forearm,¹⁴ and in muscle.^{15,16} These changes are present before the onset of clinical diabetes and some clinicians advocate the use of biopsies to facilitate the earlier diagnosis of diabetes in patients who have a strong family history of diabetes.¹⁷

Siperstein has shown that the average muscle capillary basement membrane width in normal subjects is approximately 1080 Å. By contrast, the basement membrane width in a series of 40 diabetic patients was 2278 Å. In the same work Siperstein showed an 8% incidence of capillary basement membrane thickening in normal subjects, but 98% in the diabetic groups and 53% incidence in a genetically prediabetic group.¹⁷

There seems to be little doubt that with increasing duration of diabetes the basement membrane becomes thickened in the vast majority of diabetic patients. As the basement membrane thickens and infolds, it projects into the endothelial cell cytoplasm causing formation of paraaminosalicylic acid (PAS) + material. What the PAS + material does to capillary function is unknown though some maintain it interferes with the normal capillary diffusion of nutrients and/or insulin, preventing normal metabolism in the cells. This correlates with the elevated insulin-like activity reported in prediabetes and early overt diabetes. Later, exhaustion of the beta cells and atrophy of

the islets lead to manifest carbohydrate intolerance.

The longer diabetes exists, the worse the angiopathy can become. Effective diabetic control does not prevent the vascular lesions but good control can diminish the incidence of angiopathy.¹ In addition to the structural changes of the vascular system, it has been found that during various stages of diabetes the whole blood and plasma viscosity is increased. Simultaneously, there is a tendency toward increased intravascular cell aggregation. These changes in blood and plasma viscosity and the aggregation phenomenon all play a part in a vicious cycle that impairs blood flow. Together with diminished resistance to infection, abnormal plantar pressure relationships, and peripheral neuropathy conditions arise in the diabetic foot which frequently end in amputation.

Neuropathy is common in diabetics but the problem is so diverse in its manifestations and so little has been determined about its etiology that confusion has been great.

Since the criteria for diagnosis of neuropathy vary considerably from clinic to clinic, the incidence varies all the way from 0.1% in Joslin's 1928¹⁹ survey to 93% in Collens' ²⁰ series of 1940 which was based on impairment of vibration sense. It is obvious that the harder one looks for these changes the more likely will they be found. The presence of chronic neuropathy can be ascertained by diminished ankle jerks or diminished vibration sense in the feet. Rackow found in a survey of 3500 diabetic patients that if patients over 70 years of age were excluded the incidence of absent ankle jerks is 21% and absent vibration sense 8%.²¹ Others find rates as high as 25 to 45%. Mayne's 1965 series is a careful comparison of normal and diabetic age-matched groups and reports the incidence twice as high in the diabetic group.²² Since there is a steady increase in the incidence of neuropathy in both groups with advancing age, Mayne concludes that the neuropathy of aging, as shown by impaired ankle jerks and loss of vibration sense at the ankle, is a degenerative process and probably ischemic. Neuropathy with severe pain, muscle weakness, and extensive sensory disturbance is truly diabetic.

The relationship of the neuropathies to the severity and duration of the diabetes, the age of the patient, or with other complications of diabetes is not clear. Neuropathy may occur during good

diabetic control but may also be seen with glyco-
uria. It may be precipitated by stress situations.²¹

1959	Goldenberg	PAS + thickening of vessels of skin, muscle, nerves.

Diabetic Neuropathy

Diabetic neuropathy is typically gradual in onset and chronic in character but it is possible that the onset be acute. In such instances muscular weakness and wasting are more common. Sensory manifestations predominate in the chronic form. Diabetic neuropathy may be classified under the following headings: (1) Chronic, or sensory neuropathy, (2) Subacute neuropathy which may be predominantly sensory or predominantly motor, (3) Autonomic neuropathy, and (4) Single nerve lesions.²¹

Chronic

Chronic sensory neuropathy, the commonest type of neuropathy, is frequently manifested only by absent ankle jerks, and less commonly by diminished vibration sense. The findings are distal, symmetrical, sensory, and confined to the lower limb. A burning or aching, persistent pain may be found together with muscle tenderness. It is worse at night. The onset does not usually follow periods of bad control and recovery is rarely complete.

In severe long-standing chronic neuropathy, there may be trophic changes confined to the feet and ankle which are probably due to sensory denervation particularly loss of appreciation of pain. These are similar to those found in other chronic sensory denervating conditions such as tabes, eprosy and syringomyelia. Ulcerations may appear acutely but more commonly follow the formation of a blister, trauma, or some sort of pressure from the shoe. Deformity of the toes decreases the

space available in the shoe and so increases the pressure and rubbing of the metatarsal heads.²³ Consequently, neuropathic ulcers are common on the foot and across the transverse arch on its plantar surface over the head of the first metatarsal often in association with the hallux valgus. Neuropathy of long duration also produces changes in joints, especially the mid-tarsal joint. These changes may progress to total disorganization and the production of Charcot-like joints, with swollen, deformed, hypermobile, and usually painless feet. Superficial ulceration is common and Xrays may reveal an unsuspected osteomyelitis.

Subacute

Subacute neuropathy with a major sensory component is less common and usually appears after a period of diabetic neglect or bad control or at the onset of severe diabetes. It is usually reversible. Lightning-like pain, tenderness, and paresthesiae are characteristically present. The signs tend to be symmetrical, although less so than in chronic neuropathy, and may appear in one limb before the other. Knee and/or ankle jerks may be lost and all forms of sensation may be impaired.

Subacute neuropathy with predominant motor findings of weakness and wasting of the muscles, with or without pain, also usually follow periods of bad diabetic control. The commonest presentation is with pain in one thigh which is worse at night and may be relieved by walking. It is often followed by weakness and wasting of the quadriceps. The knee jerk is usually absent but the ankle jerk may be preserved.

Autonomic

Autonomic neuropathy is the third type seen, and the manifestations which can be demonstrated most commonly are sweating, edema, changes in skin texture, impotence, diarrhea, and atony of the bladder.

Single Nerve

Single nerve lesions which may be found in the upper as well as in the lower extremities may present with acute pain followed by severe wasting of the muscles. The lesion is probably due to local injury of a nerve producing reduced conduction time and increased susceptibility to damage. The progression of a carpal tunnel syndrome in a diabetic patient is frequently more rapid and more permanent than in a nondiabetic. Nerve conduction abnormalities have been found in nearly all diabetics, with or without symptoms. It has been postulated that this tendency of diabetics to develop neuropathies causes peripheral

nerves to be susceptible to trauma and pressure and that the isolated neuropathies especially those affecting the upper limbs are due to pressures, stretchings, and compressions which less commonly produce similar lesions in the nondiabetic.

The pathology of the neuropathies is still obscure. The chief structural abnormality is severe segmental demyelination with relative preservation of axon cylinders. This is regarded as evidence that the primary disorder may be in the Schwann cells rather than in the neuron itself.^{24,25} The cause of diabetic neuropathy is unknown but various factors have been incriminated, including atherosclerosis of the vasa nervorum,²⁶ diabetic microangiopathy of the vasa nervorum with glycoprotein deposition,⁷ and other biochemical factors.

Another factor which frequently leads to foot problems in the diabetic is related to the abnormal pressure relationships between the plantar surface of the foot and stiff shoe gear. Retraction of the toes from neuropathy throws weight on the metatarsal heads, and a callus forms. Ulceration often follows attempts to remove it. This is the so-called perforating ulcer. Barrett and Mooney in a recent presentation postulated that the deformity is more responsible for the subsequent diabetic ulcer than is anesthesia.²³ Among the evidence available to support this hypothesis is the fact that transmetatarsal amputations in diabetics, by eliminating the pressure areas, are relatively successful, certainly more successful than in the nondiabetic population with distal, localized gangrene.^{28,29,30}

The methods of Brand³¹ and Harris,²³ have also shown; in a semiquantitative manner, the tremendous pressures that can be localized to one or more sites due to the deformities.

Diabetic neuropathy may also produce weakness of the intrinsic muscles of the foot resulting in impaired control of movement of the toes. The lumbrical palsy results in loss of extension at the proximal interphalangeal joints while the interosseus palsy greatly diminishes the power of metatarsophalangeal flexion. The normal but unbalanced pull of the long flexor and extensor muscles helped by shoe pressure produces crumpled, clawed toes with a strong tendency to dorsal subluxation of the metatarsophalangeal joints.

Summary

The lesions of the lower extremities of diabetics can all be related ultimately to the problems of

ischemia—the large vessel disease is quite similar to the same disease seen in nondiabetics and the small vessel disease is characteristic, perhaps even pathognomonic, of diabetes, affecting mainly capillaries, including both the vasa vasorum of the large vessels and the vasa nervorum. The latter lesion affects the autonomic nerves, the sensory

TABLE 3
Suggestions for the Care of Diabetic Feet

1. Wash feet each night with face soap and warm water.
2. Dry feet with a clean, soft rag without rubbing the skin. Dry carefully between the toes.
3. Always keep your feet warm. Use woolen socks or wool-lined shoes in the winter and white cotton socks in warm weather. Use a clean pair of socks each day.
4. Use loose-fitting bed socks.
5. Never apply hot water bottles, electric pads, or any other form of mechanical heating device to your extremities.
6. Wear properly fitting shoes and be particularly careful that they are not too tight. Use shoes made of soft leather with nonrigid shanks.
7. Cut your toenails in a very good light and only after your feet have been soaked in warm water and cleansed thoroughly. Cut the toenails straight across. Do not cut down in the corners of the nails. If your vision is impaired do not attempt to cut your toenails. Seek assistance from others.
8. Do not cut your corns or calluses. Instead, take pressure of shoe off corns, bunions, or calluses by using soft, peripheral pads or larger shoes.
9. Do not wear circular garters.
10. Do not use strong antiseptic drugs on your feet, particularly tincture of iodine, lysol, or carbolic acid.
11. Seek medical care at the first signs of a blister infection of the toes, ingrowing toenails, or trouble with bunions, corns, or calluses.
12. Do not use tobacco in any form.
13. Have some member of your family examine your feet at least once a week for blisters, sores, or other wounds.
14. Avoid getting athlete's foot. If present, be very careful how you treat it. Seek your physician's advice on the matter.

erves, and the motor nerves. Autonomic nerve changes cause altered vascular function; sensory nerve changes cause anesthesia, and motor nerve changes cause paresis and muscle imbalance. Ultimately, all three types of nerve lesions combine to create the typical cutaneous, subcutaneous and osseous lesions of diabetic feet. Undoubtedly, the same small vessel changes diminish the region's

resistance to infection as well.

Because no effective treatment exists for the primary angiopathic lesion, all present efforts must be directed at better management of the diabetic and better prophylaxis against the secondary lesions. Suggestions for the patient are listed in Table 3.

Acute Ligamentous Injuries of the Knee Joint

Treated by Surgery

DAVID E. LARSON, M.D.,* ROBERT F. PREMER, M.D.† and RAYMOND B. GUSTILO, M.D.‡

ORTHOPAEDIC SURGEONS in this country generally agree that immediate diagnosis and primary surgical repair of severe knee ligament injuries produce the optimum return of knee function.³ This report describes various knee ligament ruptures and types of surgical repair, and confirms the efficacy of immediate diagnosis and repair.

We have treated 36 knees in 34 patients at Hennepin County General Hospital in the past ten years. Males accounted for 24 of the 36 knees. Injuries affected right and left knees about equally. Although their ages ranged from 14 to 65 years, those under 30 years constituted 70% of the series (Figure).

Figure

A car striking a pedestrian produced the most frequent causes of injury. Others commonly resulted from falls or motorcycle accidents and athletic mishaps (Table 1). In most cases we could not ascertain the actual mechanism of injury.

Correct Diagnosis

Often difficult to make, the complete diagnosis depends on a careful and early examination. Because swelling, tenderness, and pain develop rapidly, the immediate post-injury period provides the best opportunity. After aspirating the knee and injecting ten to 20cc of two percent xylocaine, test for collateral and cruciate instability. If the physician does not see the patient within the first hour, spinal or general anesthesia may be necessary to overcome pain, spasm, and guarding. In many of our patients, the surgical findings demonstrated the incompleteness of the clinical diagnosis, attesting to the difficulty of evaluating these injuries. The medial meniscus and posterior cruciate especially evaded accurate evaluation.

Fractures occurred in 39% of the cases, most commonly being avulsions secondary to collateral ligament or anterior cruciate strains.

Stress Xrays may assist in confirmation of collateral ligament rupture. Of the valgus injuries receiving stress Xrays, the medial joint line opened an average of 13.5mm. All of these demonstrated at least 10mm of widening on the Xray.

Types of Injury

Valgus with external rotation produced the majority of injuries (Table 2). Eighty-six percent included disruption of the medial collateral ligament. The "unhappy triad," described in 1950 by Dr. O'Donoghue,³ consists of disruption of the

medial collateral ligament, anterior cruciate, and medial meniscus. Twenty-three percent of the medial injuries had this finding at surgery. The anterior cruciate was disrupted in 21 of 31 medial injuries.

Structures on both sides (2) (5.7%)

1—Both collateral ligaments and anterior cruciate

1—Both collateral ligaments, anterior cruciate and medial meniscus

Cruciate ligaments only (0) (0%)

Injuries to the lateral side, considered secondary to varus strain, constituted only three or 8.3% of the series. Two other knees sustained such severe injuries, that both medial and collateral ligaments were found to be interrupted. An isolated injury to the anterior cruciate did not occur in any of the knees, indicating the trend towards conservative management of this isolated problem.

Documented dislocation occurred in six of the 36 knees. The medial collateral ligament and anterior cruciate were ruptured in five of the six, although only one of the six knees had interruption of the lateral collateral ligament. Injuries associated with dislocation include disruption of the popliteal artery, one peroneal nerve paralysis, and one combined gastrocnemius and hamstring rupture.

Ligament Repairs

The surgeon must use care to determine the integrity of both deep and superficial portions of the collateral ligaments, since repair of both portions is essential. Usually both portions are rup-

tured, as seen in 28 of the 32 medial collateral ligament injuries.

When avulsed at one end, the ligament can be repaired either by stapling the attached fragment or suturing through drill holes. When torn in its substance, the ligament can sometimes be primarily sutured, or redundant tissue plicated. Direct suturing of ligament ends was used in the majority of medial collateral ligament repairs. Reattachment to bone was more often utilized in the lateral collateral ligament repairs (Table 3). The majority of the 24 anterior cruciate ruptures were repaired by reattachment to the bone (Table 4).

We found medial meniscus damage to be common, occurring in 16 of the 36 knees. Peripheral tears of the coronary ligament were resutured in five, but the remaining eleven had to be excised because the damage was more severe. Two lateral menisci were removed.

Prompt surgical repair of the third degree tears should be performed as soon as the diagnosis is reached.⁴ Surgery was accomplished within 24 hours in fifty percent of these knees, and during the first week in all but three. Six weeks of cast immobilization with the knee in slight flexion, followed by active range of motion and quadriceps exercises constitute the post-surgical program. One postoperative infection (staph aureus) occurred, resulting in limitation of knee motion.

Results

We obtained adequate follow-up in 22 patients, with an average time interval of 2.2 years. With regard to total evaluation, the patients were

pleased in 17 of the twenty-two cases. The major qualification was "stiffness" in four, and "soreness" in the other, although of these five patients, two were 65 years of age, another had sustained a complete dislocation, and one had the postoperative infection.

Instability did not recur following surgical repair. One patient described occasional giving way and the rest claimed excellent stability. Range of motion and freedom from pain were quite satisfactory in nearly all.

Ability of the patient to return to his previous activity level presents the best objective finding in assessing the results. Patients were able in every case to return to their routine activities of daily living without limitations. All but one, a construction worker, returned to previous employment. Of the 17 patients who previously participated in athletics, ten had resumed them. An additional five felt they could return, but were modifying their activity to protect the knee.

No correlation between delay of surgery and final outcome existed, nor did cruciate ligament

repair correlate with end result.

Conclusions

Knee ligament ruptures occurred primarily in the young adult, although only one-third of the cases resulted from athletic trauma. The vast majority were valgus injuries with 92% of the medial collateral ligaments torn. Stress Xrays demonstrated at least 10mm of joint line separation when the medial collateral is completely torn. Anterior cruciate tears were found in two-thirds of the knees, but never as an isolated lesion. No conclusion could be drawn regarding the importance of anterior cruciate repair. Medial meniscus tears, difficult to diagnose preoperatively, were found in nearly one-half of all the cases. Bony injuries (39%) were commonly associated with all of these cases. Excellent ligamentous stability and function resulted from surgical repair, even in the presence of complete dislocation. We found minimal interference with the post-injury activity level in most patients.

It's the Law

Death Following Penicillin Injection

An internist saw a 54-year-old man for pneumonia. He administered penicillin and gave the patient a prescription for oral penicillin. While in the pharmacy having the prescription filled, the patient died. The cause of death was anaphylactic reaction to the penicillin.

The internist stated that the patient had not advised him that he was allergic to penicillin. Indeed, one month prior to this most recent injection, the patient had been given penicillin injection with no adverse reaction. A California jury found the internist not liable for the patient's death.

Femoral Shaft Fractures in Children

Treated by Early Spica Cast

JOSEPH MERICKEL, M.D.* and WALTER INDECK, M.D.†

CHILDREN ADMITTED to the Hennepin County General Hospital during the period from April 1970 to December 1972, have been treated by an "immediate" spica casting as a definitive program for femoral shaft fractures. Of forty-one patients in the study, thirty-six had the spica program and five received the traditional traction method of treatment. This retrospective study analyzes and compares the end results.

Garrison's, *History of Medicine* credits Guy de Chauliac (1300-1368) for popularizing the treatment of femoral shaft fractures with weights and pulleys. Similar treatment programs continued in vogue for the next several hundred years. Cushing, in 1898, advocated the spica cast treatment relying on fluoroscopy to determine the fracture fragment's position. A single spica with too much padding to allow adequate counter traction and poor x-ray visualization probably combined to give less than ideal results at the end of the treat-

ment period.

Conwell, in his extensive review of *Acute Fractures of the Shaft of the Femur in Children* published in 1929, cited several orthopaedic surgeons who were treating fractured femurs in children by immediate immobilization using "pins and plaster spica." He emphasized that excellent results could be obtained by following one of three basic programs: plaster cast, plaster cast and traction, and suspension in traction. His analysis also suggested that very young patients treated by plaster, showed better results than older children.⁴

Dameron and Thompson analyzed one-hundred unselected patients treated by the spica cast method. When a fracture was well immobilized, pain was minimal, muscle spasm negligible and shortening was less likely to occur. A double spica cast was used in children to the age of fourteen and general anesthesia was used during cast application. Serial x-ray studies of the healed fractured limb revealed an average of one-sixteenth of an inch increase in length.⁵

Their conclusions were that early reduction in spica cast could be expected to offer excellent re-

Fig. 1 (A)—Initial and postreduction views.

Presented at the Annual Orthopaedic Trauma Seminar—Nov. 5th & 6th, 1971.

sults in pediatric patients. Although the authors noted no serious anesthetic complication, the need for a general anesthetic to apply the cast might be considered to be a disadvantage.

Method

As soon as the child's general condition permitted, a one and one-half spica cast was applied while the patient was under ketamine anesthesia. This agent is a non-barbiturate and produces a dissociative type of anesthesia characterized by relatively profound analgesia, but preserves pharyngeal and laryngeal reflexes. Muscle relaxation may not be as complete as under a general anesthetic. In this series there have been no anesthetic complications.

Russell's skin traction was applied immediately following admission and continued until the application of the plaster. Anesthesia was started while the patients were still in traction and after satisfactory induction, the patient was transferred to a small fracture table. Assistants were used to hold the lower extremities maintaining the fractured limb with the hip abducted 30° , flexed to 60° and the knee flexed to approximately 60° . Another team applied the spica to extend from the costal margin to the toes on the involved side and to just above the knee on the uninvolved side.

Transverse fractures were reduced when possible prior to casting, but if reduction was lost, bayonet apposition was accepted as satisfactory (Figures 1 (A) and 1 (B)). Most of the spicas were applied within three days of admission and the patients were discharged within twenty-four hours after plaster application.

Children treated with the conventional Russell's traction method, usually had other injuries or were hospitalized for extenuating circumstances.

Clinical

Leg lengths were measured on all patients of the spica group and four in the traction group and were compared to teleo-roentgenogram lengths.

Symptoms, problems and gait disorders were recorded when the patient returned for clinical appointment. In instances where patients could not be reached, these factors were checked by letters.

Results

Average ages of children treated by the two methods revealed little difference; six years by traction versus 4.3 years by plaster program.

The average hospital stays showed a much more significant difference: 36 days in the traction group and 5.3 days in the spica group.

Fig. 1 (B)—Initial and postreduction views.

Fig. 2 (A)—Five weeks in spica cast demonstrating over-riding of the femur.

Fig. 2 (B)—Six weeks in spica cast demonstrating over-riding.

Fig. 3 (A)—Follow-up at four and 10 months demonstrating progressive lengthening.

Fig. 3 (B)—Follow-up at 13 months postfracture showing 0.3 cm. of shortening.

The traction group averaged 74 days to weight bearing (36 days in traction, 38 days in a spica). Immediate spica patients averaged 60 days (three days in traction, 56 days in a spica). The difference in time between the groups may reflect a slightly older patient treated in traction.

All fractures healed. Shortening of the involved femur becomes an important potential problem with the immediate cast program [Figures 2(A) and 2(B)]. Ten of the 36 patients in this group exhibited one cm. or more of shortening on clinical measurement and three, as much as two cm. One child who had early x-ray studies demonstrated a shortening of 2.5 cm., had only 1.7 cm. of shortening at 10 months [Figures 3(A) and 3(B)]. No patient had residual disability as a result of shortening.

Four of five children treated in traction showed shortening varying from 0.5 cm., to 2.2 cm. X-ray comparisons of a child with 2.2 cm. of shortening early in his course, showed equal leg length one year following his injury. None of the patients in the traction group had residual functional problems.

Although angular deformity was present on several initial films following cast application, residual angular deformity was insignificant.

Comment

Thompson emphasized that all limbs do not

overgrow, but that transverse fractures in children under the age of six, usually exhibit this tendency to compensate. Oblique and spiral fractures in children over eight years may not exhibit significant growth stimulus. Cole, in 1925, demonstrated that compensatory growth may take place in both tibial and femoral epiphysis.³

Our results were comparable to those obtained by Thompson. Older children appeared more likely to have slight degrees of shortening, but this discrepancy may diminish in the two years following injury. The degree of compensatory growth depends upon the type of fracture and the age of the child. No patient had an unsatisfactory result in respect to leg length discrepancy or disability.⁵

Blount² cautions that "The treatment of a displaced shaft fracture with a plaster cast, requires considerable skill." McKeever stated that "The safest method of treatment of femoral shaft fracture for the average surgeon in the average hospital is traction." Both statements have some element of truth. There should be a place however in the armamentarium for the early spica casting program.

Shortening appears to be controlled by close adherence to the application technique as developed by Thompson.

The treatment of fractured femurs with early cast application decreases hospital stay with no compromise in the end result.

Course on Alcoholism and Other Drug Abuse

Sunday, July 29th through Friday, August 3rd are the dates for a "Symposium on Alcoholism and Other Drug Abuse" aimed particularly for the Rural Health and Helping Professionals. This symposium is to be held at Mt. Senario College at Ladysmith, Wisconsin and is endorsed by the Education Committee of Wisconsin Academy of Family Physicians for 33 hours of post-graduate credit.

Among the speakers will be Dr. Joe Benforado of Madison and Dr. Dan Anderson of Hazeldon Treatment Center, Center City, Minnesota.

Early registrations are being accepted. Direct your correspondence to: Dean Edwin Blackburn, Mt. Senario College, Ladysmith, Wisconsin. Registration fee: \$5.00 plus \$40.00 for the five day work-shop.

Scoliosis Treatment

Skeletal Maturity Evaluation

WALTER P. BLOUNT, M.D.* and DAVID D. MELLENCAMP, M.D.*

PRESENT DAY management of scoliosis has been significantly influenced by such orthopedic clinics as the one at Fairview Hospital, Minneapolis, directed by John H. Moe.^{4,5,10} Until the early sixties the chronologic age of the patient was generally used in establishing prognosis in the surgical treatment of scoliosis. Since then we have used the skeletal age according to Greulich and Pyle, obtained by comparing a P. A. Xray of the left hand and wrist with standard plates for boys and girls.⁸ This finding is of value only as a prognostic sign. It is useful to a limited degree in judging the likelihood of progression in an untreated patient.^{3,10}

The extensive curve of a juvenile idiopathic scoliosis can frequently be reduced to an acceptable size, and held with the Milwaukee brace, until the patient reaches the optimum stage of development for surgery, skeletal age 12 for girls, and 14 for boys.^{4,5,10} If the chronologic age is three years older or younger than the skeletal, the latter is used. If reference is to the chronologic age, the patient will be either deprived of three years of growth, or kept in the brace three years longer than necessary and operated upon at a more difficult stage of development.⁵ An assessment of skeletal age is mandatory in establishing the best time for surgery in a growing child.

It became evident that we had to find a much more accurate way of estimating spinal maturity in determining when to start weaning a patient whose deformity had been corrected by a Milwaukee brace and exercises. The parents and the patient are concerned about when and how rapidly the brace will be removed. The skeletal age can serve as a warning of the need for a prolonged course of treatment but is of no value in determining when the patient is ready for weaning,³ an entirely different problem. X-ray evidence of spinal maturity is obtained by careful study of the ring apophyses of the vertebra (Figure 1) and the

Fig. 1—12/18/69. Female skeletal age 13 + 5. Standing Xray in the brace shows developing ring apophyses on the convexity of the lumbar curve. With this degree of immaturity the patient had to wear the brace full time until maturity.

(Reproduced with permission from M. L. Verlag, Uelzen, West Germany. From Blount, Walter P. and Mueller, Karl H.: Die nicht-operative Behandlung der Skoliose mit dem Milwaukee-Korsett. Orthopädische Praxis, Heft 6/VIII: 148, June 1972.)

*Milwaukee, Wisconsin.

epiphyses of the ribs. There is no known method of estimating accurately the time of their closure in advance.^{1,7,12}

The maturity of vertebral ring apophyses is determined by a current Xray. However, their fusion to the vertebra does not necessarily permit weaning^{3,5} (Figure 2). It is only an indication for cautious removal of the brace for a trial of the stability of correction. Spinal maturity and stability of correction of a curve rarely occur simultaneously. Maturity usually precedes assured stability.

In establishing skeletal age it is important to obtain a family and menstrual history.^{4,5} The initial physical examination must include a careful evaluation of sexual development and an over-all estimate of apparent age. When the hands are normal, the skeletal age is of great value.⁸ The determination should be recorded at the initial visit, and repeated at intervals of two or three years because the relationship between chronologic and skeletal age may change considerably during development. But the bone age is only a prognostic sign and has no value in determining the patient's readiness for weaning.^{3,5,10}

For many years the iliac apophysis sign of Risser¹¹ has been tragically over-emphasized as an indication of not only spinal maturity, but of stability of correction of scoliosis. There is a vast difference between the stability of spines in treated and untreated patients. During Milwaukee brace management, the wedged intervertebral soft tissues become more rectangular in profile and are vulnerable to collapse when support is removed too soon.³ The findings of Collis and Ponseti⁶ with reference to progression in a 25 year follow-up were based upon the study of untreated patients. We do not accept their figures as prognostic for curves that have been under Milwaukee brace management.

Risser's criteria are about 85% reliable. This means that it is not an acceptable criterion for the other 15%. The only information of importance that can be learned from the iliac apophyses is that when their development is incomplete the patient is immature and must continue with brace treatment full time. Until the iliac apophyses have fused the spine is usually not mature but there is no constant relationship between the maturation of the vertebral and iliac apophyses.

The most reliable index to date of spinal maturity is the state of development of the vertebral apophyses (Figure 1) and the rib epiphyses. We

have found by clinical experience that as long as they are wide open, spinal deformities will likely progress rapidly, even if the iliac apophyses are fused. When the vertebral apophyses are nearly closed, progression is slow. Growth of the vertebral end plates has ceased before this but in the worsening or improvement of the bony elements of spinal deformity, the apophyses play an important role.^{3,10}

Normally the lumbar apophyses close before the thoracic. Not infrequently, in a primary lumbar curve of considerable magnitude, the lumbar apophyses will remain open as long, or longer, than those in the thoracic region. Conversely in a primary thoracic curve, the more cephalad apophyses will fuse even later than normal with reference to the lumbar. That there is a definite relationship between immaturity of the vertebral apophyses and the progression of the curvature is obvious to anyone who has followed a number of patients during non-operative treatment.⁵

Unfortunately we are faced with a variable time interval between complete maturation of the spines in Xray and assured stability of correction. Late follow-up of girls who were 15 at the time treatment was started, disclosed a consistent loss of correction on discarding of braces at maturity.^{3,5,10} The exceptions were the patients who wore their braces at night only until age 19 or 20. There was usually an additional disquieting loss during pregnancy. A discussion of the latter must wait for the completion of a prospective study.

The opinion based solely on reasoning, that improvement or worsening of a nearly mature scoliotic spine takes place as a result of decrease or increase of the wedging of the intervertebral soft parts, has been proved clinically by Dean MacEwen⁹ and confirmed by us. There were insuperable obstacles to the accurate measurement of the height or angles of individual interspaces or vertebrae with present x-ray technics. The findings are exact enough to prove that late worsening of a curve takes place by compression of the discs on the concave side and improvement by reversal of the process, not by changes in the vertebra.⁹

Before 1965 it was axiomatic that the older the patient was when brace treatment was started, the shorter the time the brace would need to be worn. Since then we have learned that the late-starter must wear the brace several years longer at night than the child who received it earlier. The juvenile who began treatment at age 10 may be wear-

ing it at night only by the time he is 13. While in grammar school, patients do not mind wearing the brace, but object to it during the last years of high school when maintenance of correction is so important. Rarely is there any opposition to sleeping in the brace.

In a skeletally 16 year old female, a 40° major thoracic curve that has appeared gradually and shows little deformity of the vertebral bodies but considerable wedging of several apical interspaces, is not likely to get much worse without treatment. If her deformity is not acceptable, she should have a fusion. A Milwaukee brace may correct her deformity slightly, but any improvement will be only temporary unless she continues to wear it full time for two years and at night for two or three more.⁵ Any changes in the spine will be of the intervertebral soft parts which will gradually become more stable after skeletal age 18.⁷ The clinical phenomenon of firming up has no exact anatomic parallel. The age of this developmental change corresponds roughly to that of maturation of the discs as shown at operation and in cadaver studies.^{7,12}

If this same 16 year old girl had been started on efficient non-operative treatment at skeletal age 15, when the vertebral apophyses were still

open, but the ultimate contour of the vertebral bodies was well established, she might have obtained considerable improvement of the list, the curvature, and the rib hump. These changes, also, would have occurred almost entirely by reduction of the wedging of the intervertebral discs. Without treatment her scoliosis would likely have progressed.

If her doctor had become so delighted with her improved appearance after a year of treatment that he allowed her to remove the brace during the day, and at 17 took it off entirely (Figure 2), she would have lost all of the correction of her lateral curvature. The discs would have resumed their initial profile in the A. P. Xray. The scolioses of most girls who start treatment at age 15 are not stable, even at maturity, and the brace must be continued at night until the intervertebral soft parts have firmed up. This concept makes non-operative treatment less acceptable and the problem more complicated for older patients. It does permit us to establish a more valid prognosis. If our 15 year old girl's brief treatment included well-supervised exercises and posture training, she might retain some of the correction of the curve as well as the list and rib hump. She has been prevented from becoming considerably worse. With an original curve of less than 40° , the result will be acceptable, but only because it was acceptable at the start of treatment.

If the curve had been 55° at skeletal age 15, the appearance at age 18 would probably have been unacceptable and one must concede that the effort was wasted. Correction and fusion of

Fig. 2 A—7/3/57. Female, chronologic age 11 + 9, skeletal age 13. Spinal deformity noticed by the parents January 1957 at which time the right thoracic curve measured 17° and the left lumbar 26° . The thoracic curve had progressed considerably by the time this photograph was taken. It was a typical idiopathic right thoracic curve with the torso listed to the right, the right shoulder slightly high and the scapula prominent. There was a corresponding valley on the left side.

Fig. 2 B—7/3/57. On forward bending a considerable rib hump was apparent on the right and the right convex curve persisted.

he major curve is then necessary. This greater-than-borderline curve should have been operated upon at age 15.

During the brace treatment of a 15-year-old girl, carefully made Xrays showed that there had been no change in the shape of the vertebrae but wedging of the intervertebral discs had been diminished.⁹ Some of the interspaces that had been wedge-shaped became nearly rectangular in profile. The correction of this 15 year old spine by the brace and vigorous exercises took place entirely in the intervertebral soft parts. It will not be stable enough to maintain lasting improvement until the soft parts have firmed up. Clinical research is in progress to determine the minimal time that the brace should be worn at night to assure a favorable outcome. Following skeletal maturity at 18, two years is suggested.

The time to discuss prolonged wearing of the brace is not when the maximum correction has been finally obtained but when treatment has been under way for a few months and wearing the brace at night has been found acceptable. If the patient is not willing to continue the use of the brace at night for a final two or three years, even a moderate curve should be fused by operation without delay.^{5,10}

Fig. 2 C—2/5/60. On a program of Milwaukee brace full time and exercises, the patient improved until her appearance in two years was normal. At skeletal age 15 she had been started on a weaning program. After two months she had the brace off four hours five times a week. She wore it at night until June 1959 and then she abandoned it. She retained the correction for six months until this photograph was made.

Fig. 2 D—2/5/60. There was no rib hump whatsoever on forward bending. There was slight prominence in the left lumbar region which was not present when the patient was erect.

Fig. 2 E—6/9/57. A submitted film did not show the cephalad portion of the thoracic spine but the right thoracic curve had increased to 36° and the left lumbar to 25°. Fusion of the thoracic curve had been advised. In the light of subsequent events this would have been a good plan.

Fig. 2 F—8/17/59. After two years the Xray showed perfect compensation with two curves of 21° . There was no wedging of the vertebral bodies and very little wedging of the intervertebral soft parts. The iliac apophyses had completed their excursions. The patient and her parents were delighted with the result and were most insistent on weaning, which was reluctantly permitted.

Fig. 2 H—7/6/62. On forward bending the rib hump on the right and the valley on the left are clearly visible.

Fig. 2 G—7/6/62. Three years more of vigorous activity did not impair the compensation. The torso and hip line were definitely asymmetrical, and the thoracic valley and rib hump can be seen in this photograph.

Fig. 2 I—7/6/62. In three years without treatment the right thoracic curve had progressed 11° . The patient had obviously discarded her brace too soon. Her skeletal age was now 18. By our 1973 standards she should have been wearing her brace at night only, and for another year or two.

Fig. 2 J—12/10/69. In the seven years and five months between Figures I and J, the patient lost 8°. The measurement was now 40°, five degrees worse than it was when she was first seen. She was still compensated however, and the patient and the parents were satisfied with the result. She was married and delivered a baby in March 1971. She knew that the curve had become worse and thought that the progression had been gradual during the pregnancy.

Fig. 2 K—11/17/72. She returned for examination on November 17, 1972 which was 18 months after the delivery. The right thoracic curve from T 5 to L 1 now measured 46°. This means that she had lost at least 5° since the start of the pregnancy. Vertebra was still rectangular in profile but the interspaces near the apex were more wedged than those in 2 F.

Fig. 2 L—11/17/72. She had a list to the right. A plumb line fell 5 mm. to the right of the gluteal cleft. Her shoulders were level. There was increased prominence of the scapula on the right and depth of the valley on the left. The anteroposterior diameter of the chest was greatly reduced on the left side.

Fig. 2 M—11/17/72. On forward bending the rib hump was now almost as pronounced as at the time of the first examination. The left lumbar protrusion was greater and the valley was deeper. Compensation was characteristically retained, while the patient's lateral curvature had continued to progress. This is the sad story of patients who are weaned too soon and not put back in their braces when a loss of correction is proved by Xray.

There is even wider variation in the age at which the soft parts firm up than there is in the maturation of the bony components of the spine. If laboratory and clinical research can give us accurate tests to determine the stage of development of the intervertebral soft parts, and we are able to control firming up of discs with hormones as we now accelerate the maturation of vertebrae, the weaning schedule of brace patients can be more accurately planned.

With our present meager knowledge, we can say that if a girl's skeletal age is 15 when treatment is begun, but she starts weaning at 17 and abandons her brace at 18 she will be fortunate if she loses only part of her correction. Some lose it all. If she abandons the brace completely at 17 she will likely be worse in a few years than at the start of treatment.

If juvenile idiopathic scolioses of 60° or less, with wedged apical vertebrae, are treated energetically with the Milwaukee brace and exercises, the outcome is strikingly different (Figure 3). They can be corrected dramatically. When the spines are held almost straight for several years, the wedging of the vertebrae will disappear and the bodies will be rectangular in frontal profile. These are osseous changes which mean ultimate stable correction. If a moderate curve is well straightened out (Figure 3), the child may wear the brace at night only from age 12 until maturity and not fear a loss on removal of the brace.⁴ If larger curves are reduced to only 40° , prolonged protection is necessary to assure an acceptable outcome. Fusion at skeletal age 12 may be more acceptable to the patient and the parents, and may give a better cosmetic result.

Summary

The grim outlook for older adolescents can be summarized by saying that girls of 15 with borderline curves of 50 to 55° should be fused rather than treated conservatively unless the patient is inspired to carry out a long course of treatment. Most girls with skeletal age of 13 or less with moderate curves can begin their weaning between skeletal age 17 and 18, abandon their braces at 19 and expect satisfactory results with non-operative treatment.

Scoliosis patients should have an initial sophisticated evaluation of skeletal age. During non-operative treatment the progress of spinal maturation should be followed by clinical and Xray evaluations. Most conclusive of the positive signs is

Fig. 3 A—11/21/66. Female chronologic age $11 + 3$ skeletal age $10 + 9$. The right thoracic curve and prominence of the right scapula are clearly evident. The scoliosis must have been present for a year or more.

Fig. 3 B—11/21/66. On forward bending, minimal rib prominence on the right suggested an early structural curve. This was the time to start treatment.

X-ray evidence of closure of the vertebral ring apophyses.

Spinal maturity is an indication for testing stability of correction by making a standing X-ray after the patient has been out of the brace for three hours.^{4,5} If there is no more than 3° increase of the major curve as compared with the measurement on first removing the brace, the correction is stable. The patient may be allowed to be out of the brace for three hours once a week. Gradually the frequency of the free period is increased until it is three hours daily. This program should

be continued for several months and then the test repeated for six hours. If there is a loss of more than 3° the old schedule should be resumed. Weaning to ten hours out per day should normally take a year. A girl should rarely attend school without the brace before skeletal age 17, usually 18.

It is important to distinguish clearly between skeletal age, spinal maturity and stability of correction. Accurate interpretation of these terms will aid in halting the futile use of the Milwaukee brace in situations where success is impossible.

Reference 1-12 on page 435.

Fig. 3 C—An X-ray at six foot distance with the patient standing showed clearly the structural nature of the 18° right convex curve. T 7 was wedged with diminished height on the left. The lumbar curve from T 10 to L 4 was completely overcorrectable in a supine film with voluntary side bending to the left. This functional curve was partly compensatory for the structural curve above because it stopped at L 4. The right low lumbar curve of 6° would not have appeared had the curve above been due entirely to the 16 mm. higher right ilium. With $\frac{1}{2}$ inch block under the left foot an X-ray showed improvement of the left lumbar curve. Two staples were placed on each side of the right distal femoral epiphysis to obtain slight overcorrection of the inequality. She wore her Milwaukee brace 12 hours at night with lumbar and thoracic pads.

Fig. 3 D—When the patient returned 6/8/67 after three months, X-ray showed the folly of starting with part time use of the brace. The thoracic curve had increased 11° and the lumbar was 2° greater. At skeletal age $11 + 6$ she started wearing the brace full time with daily exercise. Eight months later a standing X-ray showed that the right thoracic curve measured 16° and the left lumbar 11° .

Fig. 3 E—The brace was continued full time for two years. After one year, 7/10/68, when the inequality of leg length was slightly overcorrected, the staples were removed. On 10/17/68 Xray showed the upper curve was 9° and the lower 5° . With this correction she was allowed to be out of the brace three hours once a week, gradually increased to daily.

On 5/26/69 the correction proved stable on a standing Xray after six hours out of the brace. She was allowed to take it off for as much as six hours, but she did not go to school without the brace until the fall of 1969. Then this 14-year-old girl was happy about attending high school without the brace. A small structural curve had been recognized early and energetic treatment augmented by the equalization of leg length had provided good correction.

Fig. 3 G—10/14/71. No deformity could be detected on clinical examination. In the next 18 months she lost some weight but her appearance remained normal.

Fig. 3 F—The brace was worn at night until 2/8/73. Her skeletal age was $17 + 6$. Xray showed skeletal maturity of all epiphyses and apophyses. Correction had stabilized and she had lost nothing on this Xray after being out of the brace 24 hours. The wedging of the body of T 7 was considerably reduced. The right ilium was now 11 mm. lower than the left. The right low lumbar curve had extended up one segment to L 3 and the two lumbar curves were well compensated.

Fig. 3 H—10/14/71. On forward bending there was no rib prominence or asymmetry of the torso. She continued to wear the brace at night for four months and then discarded it to enter the Air Force. After maturity there was no likelihood of significant progression with curves as small as these.

Scapulo-Thoracic Fusion

for

Shoulder Stabilization in Muscular Dystrophy

WILTON H. BUNCH, M.D., Ph.D.*

NOT ALL PATIENTS with muscular dystrophy die in their teens. Those with the limb girdle and fascioscapulohumeral form of the disease may not have their lives shortened greatly. What is shortened, however, is their functional capacities and abilities. Deficiencies in elevation activities and the inability to stabilize the shoulder may seriously hamper vocational opportunities and interfere with activities of daily living. This paper reports bilateral scapulo-thoracic fusion as one solution to this problem.

History

One of the earliest reports of muscular dystrophy was by Meryon³ (1852) who described the disease in two of four affected brothers. The most lucid, early description was that of Duchenne¹ (1868) which presented the clinical course of 13 patients and his name has been associated with the early occurring sex linked recessive form.

In 1884 Landouzy and Dejerine² (1884) reported a group of cases in which the involvement was initially limited to the face and shoulder girdle. These cases have since been called fascioscapulohumeral dystrophy.

Clinical Course

Fascioscapulohumeral muscular dystrophy is transmitted as an autosomal dominant with a wide range of expressivity. The age of onset usually is in the second decade. The muscles most commonly involved are the serrati, trapezii, rhomboids, latissimi and the muscles about the eyes and mouth. Late in the disease the pelvic muscles may also be involved.

This form of the disease generally is benign and Walton⁴ (1961) reports that it is not unusual to find individuals who have had the disease for 40-60 years. In our clinic there are three families in which the disease is much more severe in the

Fig. 1—The range of motion of the arms and shoulders as shown in these illustrations. Note the winging and instability of the scapula.

*Associate Professor of Orthopedic Surgery, University of Virginia, Charlottesville.

children than in the affected parents.

Case Report

A 17-year-old white girl was first seen in the Orthopedic Department of the University of Virginia Hospital in September of 1970 because of her inability to elevate her arms. Two years previously she had noted aching and fatigue about the shoulders which progressed to weakness within six months. Four years prior at age 35 her mother began having similar weakness with minimal progression.

On physical examination she was able to flex her arms to 45° and abduct to 70° bilaterally. She had full active internal rotation and 20° of external rotation. All motions were accompanied by a great deal of winging of her scapula. See Figure 1. Function of the supra and infraspinatus muscles was fair, the trapezius fair, the deltoid good, and the triceps and biceps normal. When the scapula was manually stabilized against the rib cage, she was able to forward flex 140° and to abduct 150° .

Enzyme studies, electromyogram and muscle biopsy were consistent with the diagnosis of fascioscapulohu-

Fig. 2—This artist's sketch shows the ribs cleaned of periosteum and the placing of the wires.

Fig. 3—This sketch shows the wires placed through the scapula to provide fixation and the cancellous graft between the ribs.

neral dystrophy. Despite this diagnosis and her weakness, her vocational counselor was urging a career as a beautician.

Operation

The scapula was approached through an incision beginning over the medial one-third of the spine of the scapula and the infraspinatus detached subperiosteally. The scapula was then elevated and the subscapularis muscle removed subperiosteally and resected as close to the axillary border as possible. The third through fifth ribs were exposed subperiosteally for their entire circumference along a distance of about four centimeters. Care was taken to avoid the segmental artery and nerve along the inferior border of the rib. Five pieces of

number 18 wire were placed under the ribs, two under the third and fourth and one under the fifth rib (Figure 2). Each of these were passed through the scapula. A generous cortical and cancellous graft was taken from the posterior wing of the ilium and laid between and over the ribs (Figure 3). The scapula was then drawn down against this mass of bone and the wires tightened, cut and bent. This provided good fixation of the scapula against the ribs and the bone graft. The patient was placed in a bi-valved shoulder spica.

She was kept in the shoulder spica for three months. Xrays then showed solid fusion between the ribs and scapula. One year later she returned requesting surgery for the opposite side which was treated in the similar manner.

Postoperative Status

At 30 and 18 months postoperatively she has 160° of flexion, 130° of abduction, 30° of external and 80° of internal rotation of her humerus. Her scapulae are stabilized and cosmetically improved (Figure 4). She is able to comb or brush her hair. She can dress and feed herself but is somewhat limited in dressing in that she must fasten her bra in front.

The Table shows her pulmonary function tests before and after operations. The rib fusions have reduced her vital capacity but she has noticed no limitation in activities.

TABLE

	Vital Capacity		
	Predicted	Measured	Per Cent
Preoperative	3625 cc	3415 cc	94%
After First Fusion		3065 cc	85%
After Both Fusions		2631 cc	74%

This data shows the effect of bilateral fusion of the scapula to the rib cage on the vital capacity. The stability was achieved at the cost of 800 cc of vital capacity.

Discussion

Various procedures have been proposed to stabilize the scapula; of these, muscle transfers and

Fig. 4—The postoperative range of motion of the arms is shown in these illustrations. Note the stability and cosmetic appearance of the scapula.

fascial tenodesis predominate. Scapulo thoracic fusion has not, to the author's knowledge, been previously reported. In this girl, fusion of her scapula to her rib cage has provided permanently increased function.

Rigidity has been accomplished at the cost of compromise of her vital capacity. If this had been reduced at onset, such a procedure would be inadvisable. It might be possible that one side could be fused providing excellent stability and fascial tenodesis used on the other side. It is also likely that fusion of only two ribs and the one intervening space would provide adequate stability,

thereby reducing the effect on the vital capacity.

The position of the scapula is critical to permit maximum abduction. The first 30° of abduction occur at the scapulo-humeral joint. The remaining abduction occurs at both the scapulo thoracic and scapulohumeral joints in the ratio of 1:2. If the scapulae were fused in vertical position, much of the remaining motion would be lost. By placing the scapula in 10-15° rotation, an additional 20-30° of abduction can be obtained thus giving a total abduction of 130°. There is no apparent loss of adduction with this position.

Minnesota Society of Clinical Pathologists

Dr. Donald J. Nollet has been elected President of the State Society of Clinical Pathologists succeeding Howard Taswell of Rochester.

A pathologist for 18 years at Hibbing General Hospital, Dr. Nollet has been a member of the Committee on Blood and Blood Banks of the State Association for many years. He also served on the Food and Drug Administration's Diagnostic Products Advisory Committee (HEW).

American Psychiatric Association

All psychiatrists who have not already taken the Psychiatric Knowledge and Skills Self-Assessment Program (PKSAP), are urged to apply for it by writing to the APA, 1700 18th Street, N.W., Washington, D.C. 20009. The test stresses patient management problems, allows participants to score themselves in relation to peers, and earns credits for continuing medical education.

Cover Photograph

"Iron Creek"

Dr. H. Dawes Miller's summer home is located in a remote section of the Black Hills National Forest, and about one and a half blocks from his home is "Iron Creek" pictured on this month's cover. He told the editors that this valley is a most beautiful spot, and each summer he searches out with his camera unusually lovely portions of the valley. He finds that one year is more beautiful than the last. The valley itself is located between two highways, two and a half miles from one and four and a half miles from the other with ten bridges coming in from one and seven bridges and six fords the other way.

Dr. Miller is Director of Medical Education at Fairview Hospital, Minneapolis, an amateur radio operator and enthusiastic photographer.

Distal Humerus Fractures

Transolecranon Approach

PHILIP HALEY, M.D.,* JOSEPH TAMBORNINO, M.D.† and RAMON B. GUSTILO, M.D.‡

METHOD OF OSTEOTOMY

Figure 1

EXPOSURE AVAILABLE BY OSTEOTOMY

Figure 2

INTERNAL FIXATION OF OSTEOTOMY

TWO PARALLEL STEINMAN PINS
AND TENSION WIRE TIED
IN FIGURE OF EIGHT

Figure 3

THIS IS A review of the transolecranon approach to distal humerus fractures and the records of seven patients whose fractures were operated this way.

A necessary premise is that all fractures presented required open reduction and internal fixation; therefore, attention will be focused on a surgical technique rather than on a principle of fracture treatment.

The records of seven patients were examined: two from Hennepin County General Hospital, one from St. Paul Ramsey Hospital and four from private hospitals in the Twin Cities.

Although this surgical approach had been described previously Dr. Cassebaum⁴ was the first to present a series of patients in which this technique was used exclusively. A number of articles on the subject have appeared since and refer to Dr. Cassebaum's as their source.

The method is known in other countries and some of the literature would imply that it is frequently used.

Extensive exposure of the elbow joint and prevention of adhesions are said to be the advantages. The disadvantage is that it necessitates further repair of an already complicated fracture. Cassebaum does not feel that this approach is more traumatic than incision through the triceps.

Technique

Two skin incisions have been recommended. Most authors use a posterolateral longitudinal incision, but there is also a Y-shaped incision centered just distal to the olecranon. After incision, the very next step is identification and isolation

*Orthopaedic Resident, Hennepin County General Hospital, Minneapolis.

Presented at the Ortho/Trauma Seminar, November 3 and 4, 1972, Hennepin County General Hospital.

of the ulnar nerve. It must be retracted safely out of danger.

The olecranon will shortly be osteotomized, but first consider how it will be repaired. If a screw is to be used, it is advisable to pre-drill so reduction of the osteotomy will be correct.

The olecranon is sectioned obliquely, by V-cut pointing distally, or transversely at a point 2.5 centimetres distal to its tip. Expose the elbow joints and the fracture fragments so the fracture can be examined and reduction can be practiced. After fixation and stabilization of the fracture, the osteotomy can be repaired with tension bands

or a screw. The surgeons of the Association for the Study of Internal Fixation use both a malleolar screw and a tension band. Cassebaum uses a single screw placed obliquely from the olecranon through the cortex of the ulna, distal to the osteotomy. Figures 1, 2 and 3 depict substantially this procedure. The ulnar nerve should be transposed anteriorly if its course is in any way jeopardized by fracture fragments or fixation devices.

After surgery, the type and time of immobilization will depend on the stability of the osteosynthesis. Early motion is a goal of the internal

TABLE 1

Case	Age	Associated Injuries	Complications	R O M	Notes

Fig. 4—Distal humerus fracture sustained in a fall.

fixation and most references indicate this should be started as soon as comfort and stability allow. The fixation devices should be removed at a later date, since this improves function.

Seven cases have been operated this way. A summary of each is presented briefly in Table 1. Figures 4, 5 and 6 are representative of the oste-

otomy of the olecranon and the internal fixation of the fracture.

Evaluation of Results

There have been several methods of grading results published. Drs. Bryan and Bickel³ at the Mayo Clinic have classified results according to

Fig. 5—Open reduction and internal fixation. The olecranon has been osteotomized transversely.

Fig. 6—Appearance of elbow two months post fracture, after removal of Steinman pins.

three of these and found them to be comparable. The results of the cases presented here are graded similarly, but with minor variation.

The standards for an excellent result require a pain-free elbow with a nearly normal range of motion. A good result consists of range of motion 30 to 115 degrees with or without mild symptomatology. A fair result includes significantly decreased range of motion and moderate symptomatology. Pain, deformity, instability, or greatly diminished range of motion constitute a poor result.

TABLE 2
Criteria for Evaluation

Excellent:	Painfree
	Near normal range of motion
Good:	Range of motion 30-115
	Mild symptomatology
Fair:	Significantly decreased range of motion
	Moderate symptomatology
Poor:	Pain, deformity, instability
	Greatly decreased range of motion

By these references, the seven cases presented include three good, three fair, and one poor result. No excellent result was obtained. The poor result was in a patient who had originally achieved 60° total flexion-extension and then regressed to 35°, from 60 to 95. She also had an ulnar nerve palsy.

Discussion

This is a fairly uncommon fracture and general agreement is that it is a difficult fracture to treat since regardless of the method of management, some limitation of elbow function is to be expected. The trend at this time is toward open reduction and internal fixation on the assumption that this will permit more nearly anatomical restoration of the fracture and earlier use of the joint. Results

of these fractures treated this way will be a reflection of surgical methods.

TABLE 3
Results and Evaluation

Case	R O M	Notes	Evaluation
1	20-130 (110)	Resolving slight ulnar weakness and hypesthesia	Good
2	28-130 (102)	Slightly limited supination	Good
3	30-115 (85)	Slight morning stiffness in elbow and wrist	Good
4	60-95 (35)	Ulnar nerve palsy	Poor
5	30-95 (65)	Ulnar hypesthesias and weakness	Fair
6	20-90 (70)	Slight ulnar weakness and hypthenar atrophy	Fair
7	30-90 (60)	Slightly limited shoulder motion	Fair

Since only seven cases are presented, each with limited time of follow-up, there is too little evidence to argue convincingly that these fractures should be opened or that if they are opened, that this is the technique of choice. There is already considerable literature expressing the value of operation and a small bit concerning this method. These cases add to the information available on this technique and would indicate, if time will bear it out, that comparable results are attainable this way.

Olecranon osteotomy is a practical approach to this articular fracture because it provides a complete view of the fracture, it is not technically difficult and, depending on the plane of the osteotomy, it need not add further damage to the articulating surfaces.

This approach should be considered when preparing to operate on distal humerus fractures.

Acknowledgment

We would like to acknowledge Dr. Thomas Comfort and Dr. Peter Strand for use of some of their cases in this presentation.

“Antiacid” action for ulcer patients..

one of the many things you need in an anticholinergic.

Pro-Banthine is provided in several different dosage forms and combinations which will meet virtually any clinical need. It is just as versatile in filling patient needs, among which are:

"Antiacid" action—Pro-Banthine® (propantheline bromide) reduces gastric secretory volume and resting total and free acid.

"Sustained" action—Pro-Banthine P.A.® (propantheline bromide) contains 30 mg. of the drug in the form of sustained-release or timed-release beads; on ingestion about half of the drug is released within an hour and the remainder continuously as earlier increments are metabolized.

High-level anticholinergic activity is maintained all day and all night in most patients with only two tablets every eight hours.

"Analgesic" action—Pro-Banthine helps to control the acid-spasm-pain complex.

A **"diagnostic tool"**—Pro-Banthine may be used parenterally to immobilize the duodenum for more revealing roentgenographic appraisal through hypotonic duodenography.

Pro-Banthine is considered adjunctive in total peptic ulcer therapy that may include diet, conventional antacids, bed rest, and other supportive measures.

Vigorous anticholinergic action — Pro-Banthine® Vials, 30 mg., are for intramuscular or intravenous use when prompt and vigorous anticholinergic action is required.

Mild anticholinergic action—Pro-Banthine® Half Strength, 7.5-mg. tablets, for more exact adjustment of maintenance dosage in mild to moderate gastrointestinal disorders.

Indications: Pro-Banthine is effective as adjunctive therapy in the treatment of peptic ulcer. Dosage must be adjusted to the individual.

Contraindications: Glaucoma, obstructive disease of the gastrointestinal tract, obstructive uropathy, intestinal atony, toxic megacolon, hiatal hernia associated with reflux esophagitis, or unstable cardiovascular adjustment in acute hemorrhage.

Warnings: Patients with severe cardiac disease should be given this medication with caution.

Fever and possibly heat stroke may occur due to anhidrosis. In theory a curare-like action may occur, with loss of voluntary muscle control. For such patients prompt and continuing artificial respiration should be applied until the drug effect has been exhausted.

Diarrhea in an ileostomy patient may indicate obstruction, and this possibility should be considered before administering Pro-Banthine.

Precautions: Since varying degrees of urinary hesitancy may be evidenced by elderly males with prostatic hypertrophy, such patients should be advised to micturate at the time of taking the medication.

Overdosage should be avoided in patients severely ill with ulcerative colitis.

Adverse Reactions: Varying degrees of drying of salivary secretions may occur as well as mydriasis and blurred vision. In addition the following adverse reactions have been reported: nervousness, drowsiness, dizziness, insomnia, headache, loss of the sense of taste, nausea, vomiting, constipation, impotence and allergic dermatitis.

Dosage and Administration: The recommended daily dosage for adult oral therapy is one 15-mg. tablet with meals and two at bedtime. Subsequent adjustment to the patient's requirements and tolerance must be made.

Pro-Banthine P.A.—Each tablet of Pro-Banthine P.A. (propantheline bromide) contains 30 mg. of the drug in the form of sustained-release or timed-release beads; on ingestion about half of the drug is released within an hour and the remainder continuously as earlier increments are metabolized. Thus the result is even, high-level anticholinergic activity maintained all day and all night in most patients with only two tablets daily. Some patients may require one tablet every eight hours.

The contraindications and precautions applicable to Pro-Banthine 15 mg. should be observed.

How Supplied: Pro-Banthine is supplied as tablets of 15 and 7.5 mg., as prolonged-acting tablets of 30 mg. and, for parenteral use, as serum-type vials of 30 mg.

Editorials

John H. Moe, M.D.

JNTIRING DEDICATION, industry, resourcefulness and humility epitomize John H. Moe, retiring Professor and Chairman of the Department of Orthopaedic Surgery at the University of Minnesota, for whom this issue is dedicated. He has devoted thirty-two years of his life to orthopaedic surgery—the training of residents and the care of patients, particularly with problems of scoliosis of the spine.

In his early years of medical practice, Dr. Moe tackled the most challenging and difficult problem in orthopaedic surgery at that time with all his human resources—the curvature of the spine. He labored continuously many hours a day studying the basic types of scoliosis, analyzing critically the progression of the deformity and improving the existing treatment of scoliosis and became the leading authority on this neglected problem. Dr. Moe became very skillful, particularly in the application of the Risser's cast in achieving correction and the fusion technique and he developed a meticulous facet fusion with bone graft, hence called the Moe Facet Fusion. Dr. Moe doing a scoliosis fusion could be compared to an artist doing his masterpiece for he achieved correction better than most. His analysis and reporting of results were honest and critical and his fusion rate and correction of deformity surpassed his predecessors. Moe operated on kypho-scoliotic deformity most orthopaedic surgeons refused to do.

One singular trait of his was to recognize clinical advances in a rapidly changing medical world. With the advent of the Harrington rod instrumentation and its application, he immediately realized

the vast potential of this device in the correction of scoliosis. Good correction of the most severe deformity of the spine, which in the past had been treated by conscious neglect or a common medical phrase, "nothing can be done about it!" presented no problem to him.

Along with his well-known ability on the surgical methods of correcting the deformity of the spine, Dr. Moe adapted the Milwaukee brace, devised by a long time friend, for the correction of scoliosis and mild curvature of the spine in adolescence. The best scoliosis center and teaching seminar in the country was organized by him.

In 1957, when he became head of the Division of Orthopaedic Surgery at the University of Minnesota, he applied his full energy to the development of the program. His residency program is a total complement of quality and quantity of reconstructive surgery and trauma in adults and children involving six major institutions. In a short period of time, his orthopaedic residency program attained recognition internationally as an excellent and well rounded program. To attest to the excellence of his program at the University of Minnesota, over ninety licensed medical physicians applied for four residency positions in 1972. He challenges and demands from his residents 100% dedication to their job.

In recognition of his contributions in orthopaedic surgery both as an educator and a clinician, his colleagues bestowed upon him the highest honor, the presidency of the American Orthopaedic Association in 1972. In spite of all of his accomplishments in orthopaedic surgery, John remains a

Bones Backs and Braces

"The axe slipped and cut off my leg. So I went to the tinsmith and had him make me a new one out of tin."

MINNESOTA MEDICINE observes the imminent academic* retirement of John Moe, chairman of the department of orthopedic surgery at the University of Minnesota devoting the May issue to that specialty. Orthopedics has but one derivational meaning, straight children, and Moe, a purist, has chosen that description to define his goal in his specialty. His life work has been devoted to the correction of the wayward deviation of the adolescent spine. He has become the acknowledged authority on youthful scoliosis and his legacy to his students and colleagues in the craft of bone disease is the successful treatment of spinal curvature.

MINNESOTA MEDICINE has published some of his communications in this field†

Since World War II, orthopedics, in common with all branches of medicine, has undergone revolutionary change. Moe's aggressive therapy for increasing spinal deformity is an example of remarkable change in therapeutic approach. Another is the use of prostheses to replace ball and socket and hinge joints for fracture and other destructive processes.‡ Orthopedics today can replace destroyed joints with plastic and metal. We are in the era of the Tin Woodman.§ What was hopeless joint deformity and disability yesterday represents only an operative challenge today.

MINNESOTA MEDICINE is indebted to Raymond Gustilo, guest editor, former resident under John Moe in Orthopedics at the University of Minnesota (Minneapolis) for this issue, a work of love.

Reuben Berman, M.D.
Editor

*Dr. Moe will continue in active practice in his chosen field of scoliosis.

Respiratory Assistance in the Newborn

THE EXCELLENT ARTICLE ON RESPIRATORY ASSISTANCE by Burke-Strickland* summarizes the various mechanical modalities available for the support of the neonate with respiratory fatigue progressing to insufficiency. Diagrams to elucidate the technical construction of the various systems are an excellent complement to the article. These systems require meticulous observation and frequent adjustments by both attending physician and nurses. The complications of such modalities of assistance have also been presented. Infection due to bacterial contamination in the water reservoir attached to the respirator tubing should also be mentioned to stress the need for meticulous surveillance of

the apparatus as well as the patient.

This article discusses the scientific techniques that have been devised to assist the neonate whose aberrant pulmonary physiology produces progressive respiratory distress. The physician must decide when the neonate is beginning to develop respiratory fatigue and when it is necessary to institute appropriate assistance or to transfer the child to an appropriate center before apnea occurs. The frequent, careful assessment of the respiratory pattern and associated biochemical determinants by attending physician and nurses is the only way that this potential need for respiratory assistance can be decided. As a result of careful monitoring, quality survival of more distressed neonates can be achieved.

Phillip A. Rierson, M.D.
Minneapolis, Minnesota

"The Majority of Men Live Lives of Quiet Desperation" - Thoreau

Thoreau's sad, brutal quotation reflects with disquieting honesty our human condition.

I'm Ted Irwin. For most of us, there is precious little joy in this world and plenty of hard work. But I think you'll find owning a sailboat is a sure-fire cure. It offers a sense of well-being, solitude, friendship — a place to sort things out and an excuse to find time enough.

That's why I hope you will write for our catalog of nine remedies. You take them with water.

Ted Irwin
designer/builder/sailor

IRWIN YACHTS — for the happy minority

Infectious Complications following Abortion

PERFORMING ABORTIONS on an ambulatory basis has recently received much publicity. The Supreme Court's decision which ruled abortion in the first trimester a procedure without controls has increased the interest of both the medical and non-medical public in this practice. A recent article in this journal implied that ambulatory abortion was a benign, almost perfectly safe method of terminating pregnancy in the first trimester.

Gaziano and Kaplan in the April issue* of MINNESOTA MEDICINE remind us that there are definite hazards to legal abortion and report a series of post-abortion infections. These infections probably would not have appeared in the morbidity statistics of the clinics in which the abortion was performed because the infection occurred after the patient was hundreds of miles from the abortion facility.

Legal abortion was touted as a measure to eliminate the risk of infection that frequently followed criminal abortion. Though recent articles have emphasized the decrease in hospital admissions for infected criminal abortions, this report is one of the first to point out that infection may also be a significant problem in legal abortion.

Non-adherence to the rules of strict sterile technique as practiced in the hospital operating room may extract a costly price in terms of post-abortion infection. Though the type of facility in which these ambulatory abortions were performed is not stated, the article points out one real hazard of this approach. Although a strict sterile surgical technique removes the abortion from the non-medical procedure atmosphere that the "free standing" clinic promotes, it better protects the life and health of those women who choose to be aborted. The minimal sterile technique used in "free-standing" or ambulatory abortion clinics is to be deplored.

Though at the moment there are no legal controls on who, where, or when abortions may be done in the first trimester of pregnancy, Gaziano and Kaplan's article should force us to consider some type of quality control on abortion facilities and procedures. If abortion is to be performed as an ambulatory service it should be done in a "surgi-center" or outpatient operating room type of facility in which strict sterile surgical technique is maintained.

The incidence of infection following legal abortion in this country has not been established. Unless accurate, complete follow-up and reporting is required, the exact risk of post-abortion infection will never be known.

Peter Fehr, M.D.

Letter to the Editor

Concurrence of Achalasia with Adenocarcinoma of the Stomach

DOCTOR FROMKE in his editorial "Concurrence of Achalasia with Adenocarcinoma of the Stomach" in the January issue, 1973*, made several good points. I also agree that it is difficult to make a diagnosis of carcinoma in some of these patients. This problem should by and large be alleviated by treating the patient as soon as the diagnosis is made. Treatment should consist of either

pneumatic bougienage, or the Heller procedure. No patient should be treated by either of these methods without first being esophagoscoped. With flexible fiberoptic esophagoscopy available in this community to the extent that it now is, there should be no reason why this should not be performed routinely. The procedure is no longer uncomfortable or difficult.

Michael Levy, M.D.
Minneapolis, Minnesota

Letter to the Editor

Operation on Demand?

The word "abortion" is derived from the Latin meaning "incomplete development." It may be defined as an "immature product, a misshapen thing, a monstrosity."

Spontaneous abortion is the physiologic process occurring usually when the embryo has been imperfect in its development—a mercifully divine solution for a mishap of Nature; but unfortunately, spontaneous abortion does not always occur, and a deformed or abnormal baby may be born: the result of measles, syphilis, inbreeding, idiocy, some types of criminality, some drugs, inherited congenital defects and diseases, and some mental or neurologic disorders.

Induced abortion is a minor surgical procedure designed to terminate the development of the embryo when the life or health of the mother or the fetus may be at stake.

Only after laws were passed designed to discourage unethical doctors from doing abortions in normal pregnancies, when there were no hazards, the term accumulated an immoral-sounding eponym, and became a "criminal abortion." With these laws the responsibility of performing an abortion was taken from the doctor, even though he may have thought the procedure necessary to save the life or health of the mother or child. The responsibility for the decision was, in effect, turned over to the legal profession, and the physician who performed the abortion for any one of a host of medical reasons, not specified in the law, became liable for criminal prosecution, a jail term and a revocation of his medical license.

Now, the United States Supreme Court has indicated that the abortion laws are unconstitutional, and the decision to do the operation, no matter what the indication, has reverted to the doctor where it should have remained. Or has the decision, in effect, now been transferred on demand to the wife or husband, the unmarried woman, the pregnant teenager, the mistress or her paramour, or to an advocate of population control?

Certainly our medical ethics should move out of the bleachers—quickly—into a box seat. Never in the history of Medicine has the decision for the need of any surgical operation been the prerogative of the patient. The patient, of course, may accept or reject the decision of the surgeon, but the responsibility of determining the medical indication for any operation has always been, and should remain, with the physician. Would the ethical physician, on demand, remove a normal finger, an eye, an ear, a uterus? He would not!

For now, during a temporary period of floundering, a few unthinking doctors may briefly disregard their avowed ethical code; but most doctors will continue to practice within the time-honored ethics of their noble profession. They will make their decisions to recommend the abortion procedure on the basis of the health or the life of the mother or the fetus.

"On demand" is not an indication!

Carl O. Rice, M.D., Ph.D.
Editor Emeritus

The Minnesota State Medical Association's position with respect to abortion, in the wake of the recent Supreme Court decisions, was presented to the Minnesota State Legislature recently by Dr. Richard Anonsen, speaker of the House of Delegates. The position paper states that with respect to all abortions the Association recommends that they should be performed only by a licensed physician, and that with respect to abortions performed during the first trimester, the Association recommends that no other restrictions be placed upon abortions.

Decubitus Ulcers Yield to

Travase[®] Ointment

brand of **Sutilains**

Before treatment, necrotic matter coated the inner surfaces of this decubitus ulcer.

After six days of TRAVASE therapy, debridement is nearly complete and granulation evident.

ive Therapy—Observe Its Effects in 48 hours
The recommended nursing technique is applied without deviation, this procedure can show a visible improvement within 48 hours of treatment. If no dissolution of slough occurs by then, further application is unlikely to be rewarding. Take a break in procedure, usually due to use of drying or antiseptic agents which impair the effectiveness of the enzyme in TRAVASE).

Observation and photos by Kathleen Brough, M.D., Marion County Home, Indianapolis, Ind.

Travase® Ointment brand of Sutilains

APPLICATION TECHNIQUE: TRAVASE Ointment is indicated as an adjunct to established methods of wound care for biochemical debridement. It dissolves and facilitates the removal of necrotic tissues and purulent exudates.

TRAVASE enzymes are selective. Virtually inactive on viable tissue. When this recommended nursing technique is followed without deviation, this procedure can generate visible improvement within 48 hours . . .

(Ulcer being irrigated)
Thoroughly cleanse and irrigate the wound area using only sterile water or sodium chloride solution. Be sure to cleanse the wound of any antiseptics or heavy-metal antibacterial agents which may interfere with the enzyme activity.

Thoroughly soak the wound area. Where practical, tubbing or showering is suitable. Or wet soaks with gauze pads may be used. Remember to avoid chemical cleansing agents which may interfere with the therapy.

With a sterile cotton swab or finger cot, apply a very thin layer of TRAVASE Ointment. The ointment spreads easily and only a small amount is needed (a small dab of ointment will cover an area as big as the back of a hand).

Be sure, though, to rub the ointment well into every crack or crevice of the wound and overlap the surrounding skin one-fourth to one-half inch beyond the area to be debrided—to be sure of complete coverage.

Apply loose, wet dressings, thoroughly soaked in sodium chloride solution or sterile water to the area to be debrided only.

Cover the moist dressings with an occlusive wrap (Saran wrap, Telfa Pads, or other plastic wrappings) to keep wound site moist. Do not extend occlusive wrap over 1/2 inch beyond area to be debrided.

When changing dressing, gently wipe away the dissolved material. Repeat the complete dressing procedure, including application of TRAVASE Ointment, four times daily.

The ulcer shown in these photos is simulated on a model in order to demonstrate the correct TRAVASE application technique.

Deerfield, Illinois 60015

Name _____

Title _____

Institution _____

Street _____

City _____ State _____ Zip _____

Please send:

_____ Additional Information on TRAVASE® Ointment (brand of Sutilains)

_____ In-service training program

_____ Comment _____

DESCRIPTION: TRAVASE® (brand of sutilains) Ointment is a preparation of proteolytic enzymes, elaborated by *Bacillus subtilis*, in a hydrophobic ointment base consisting of 95% white petrolatum polyethylene. One gram of ointment contains approximately 8 units* of proteolytic activity.

ACTION: TRAVASE Ointment selectively digests necrotic soft tissue by proteolytic action. It dissolves and facilitates the removal of necrotic tissues and purulent exudates that otherwise impair formation of granulation tissue and delay wound healing (4).

At body temperatures these proteolytic enzymes have optimal activity in the pH range from 6.0 to 6.8.

INDICATIONS: For wound debridement (1,2)—TRAVASE Ointment is indicated as an adjunct to established methods of wound care for biochemical debridement of the following lesions:

- Second and third degree burns,
- Decubitus ulcers,
- Incisional, traumatic, and pyogenic wounds,
- Ulcers secondary to peripheral vascular disease.

CONTRAINDICATIONS: Application of TRAVASE (brand of sutilains) Ointment is contraindicated in the following conditions:

- Wounds communicating with major body cavities,
- Wounds containing exposed major nerves or nervous tissue,
- Fungating neoplastic ulcers,
- Wounds in women of child-bearing potential—because of laboratory evidence of effects of TRAVASE upon the developing fetus.

WARNING: Do not permit TRAVASE Ointment to come into contact with the eyes. In treatment of burns or lesions about the head or neck, the ointment inadvertently come into contact with the eyes, it should be immediately rinsed with copious amounts of water, preferably sterile.

PRECAUTIONS: A moist environment is essential to optimal enzyme activity. Enzyme activity may also be impaired by certain agents such as several detergents and antiseptics (benzalkonium chloride, hexachlorophene, iodine, and nitrofurazone) may render the ointment ineffective to the action of the enzyme (3). Compounds such as containing metallic ions interfere directly with enzyme activity to a slight degree, whereas neomycin, sulfamylon-streptomycin, and other antibiotics do not affect enzyme activity. In cases where adjunctive topical therapy has been used and no dissolution of slough occurs after treatment with TRAVASE Ointment for 24 to 48 hours, further application, without interference by the adjunctive agents, is unlikely to be rewarding.

In cases where there is existent or threatening invasive infection, appropriate systemic antibiotic therapy should be instituted concurrently.

Although there have been no reports of systemic allergic reactions in humans, studies have shown that there may be an antibody response in humans to absorbed enzyme material.

ADVERSE REACTIONS: Adverse reactions consist of mild, transient pruritus, paresthesias, bleeding and transient dermatitis. Pain usually controlled by administration of mild analgesics. Side effects are usually enough to warrant discontinuation of therapy occasionally have been reported.

If bleeding or dermatitis occurs as a result of the application of TRAVASE (brand of sutilains) Ointment, therapy should be discontinued until the reaction has subsided. Toxicity has been observed as a result of the topical application of TRAVASE Ointment.

Dosage and Administration

STRICT ADHERENCE TO THE FOLLOWING IS REQUIRED FOR OPTIMUM RESULTS OF TREATMENT

1. Thoroughly Cleanse and Irrigate Wound Area with sterile water or water solutions. Wound MUST be cleansed of any antiseptics or heavy-metal antibacterials which may denature enzyme activity. Substrate characteristics (e.g., Hexachlorophene, Silver Nitrate, Benzalkonium Chloride, Nitrofurazone, etc.).
2. Thoroughly moisten wound area either through tubbing or wet soaks (e.g., sodium chloride or water solution).
3. Apply TRAVASE Ointment in a thin layer assuring in complete coverage of the wound and complete wound coverage 1/4 to 1/2 inch beyond the area to be debrided.
4. Apply loose wet dressings.
5. Repeat entire procedure 3 to 4 times per day for best results.

How Supplied

3P3002 TRAVASE Ointment is supplied sterile in one-half ounce (14.2 g.) containing 82,000 casein units of sutilains in a hydrophobic ointment base.

The ointment must be stored under refrigeration at 2° to 10° (35° to 50° F.).

2 ways to provide a daily therapeutic supply of Vitamin C: 15 baked potatoes (skins and all!) or one capsule of Allbee® with C

About 20 mg. Vitamin C in one baked potato (2½" diameter).

To many people the evening meal just isn't complete without potatoes. But your patient would have to eat 15 of them (skins and all!) to get as much Vitamin C as is contained in just one Allbee with C capsule taken daily. A bottle of 30 (month's therapeutic dose) supplies as much ascorbic acid as 450 potatoes, plus full therapeutic amounts of the B-complex vitamins. For the patient who is counting calories, Allbee with C is small potatoes because the B's and C are water soluble. Consider the number of calories in 15 potatoes, not to mention the mountain of butter and sour cream. Allbee with C is available at pharmacies in the handy bottle of 30 and the economy size of 100 on your prescription or recommendation.

A-H ROBINS

In Memoriam

ROBERT E. KOHLHASE, M.D.

Dr. Robert E. Kohlhasé, Minneapolis physician died March 7 at the age of 47. Born in New York City, Dr. Kohlhasé attended the University of Minnesota Medical School after his family moved to Minneapolis.

He was a member of the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Dr. Kohlhasé is survived by his wife, Shirley, daughter Laura and three sons, Bruce, Brian and Mark.

RALPH T. KNIGHT, M.D.

Dr. Ralph Knight, 86, Minneapolis anesthesiologist, died October 20. He was the first faculty member of the University of Minnesota to devote himself to the full-time study of anesthesiology and served as Director of the Division of Anesthesia from 1920 to 1954, when he became Professor Emeritus. During this period he trained 123 resident physicians in anesthesiology.

Born and educated in Minneapolis, Dr. Knight was a member of the Minneapolis Surgical Society, American Society of Anesthetists, Hennepin County Medical Society and the American Medical Association. He was a Life and 50 Club Member of the Minnesota State Medical Association and a fellow of the American College of Surgeons.

Dr. Knight is survived by his wife, Clara, daughter Barbara and sons, James and Thomas. Dr. Roy R. Knight of Minneapolis is his brother.

GEORGE N. RUHBERG, M.D.

Dr. George W. Ruhberg, born in Grafton, North Dakota in 1893, died January 23, at his home in Santa Barbara, California. He had attended the University of Minnesota Medical School and practiced for 25 years in St. Paul as attending neuropsychiatrist at Ancker Hospital and Gillette State Hospital. Dr. Ruhberg was also assistant clinical professor of neurology and psychiatry at the University of Minnesota.

A past president of the Ramsey County Medical Society and the Central Neuropsychiatric Association, Dr. Ruhberg was also a charter member of the Hundred Club of St. Paul and a life member of the St. Paul Historical Society. He was a member of the American Medical Association and an Associate and 50 Club Mem-

ber of the Minnesota State Medical Association.

Dr. Ruhberg is survived by his wife, Gertrude, four daughters and a son.

PAUL F. MEYER, M.D.

Dr. Paul Meyer, 76, Faribault physician and surgeon, died February 13, in Tampa, Florida, while visiting his daughter there. He was born in Sedalia, Missouri, and in 1908 his family moved to Faribault. In 1925 he started the practice of medicine in Faribault and remained there for 48 years.

He was a member of the American Medical Association and the American Academy of Family Practice, a past president of the Rice County Medical Society and a Life and 50 Club Member of the Minnesota State Medical Association.

Dr. Meyer is survived by his wife, Dorothy, daughter Jan, and sons, Doctors Robert and Richard Meyer.

STUART WILLIAM HARRINGTON, M.D.

Dr. Stuart W. Harrington, 83, internationally known breast and lung surgeon at the Mayo Clinic, died March 7. He was also professor emeritus of surgery.

In 1912 as a member of the University of Pennsylvania football team, he was named to the Walter Camp All American Football Team.

He was a former president of the American Association for Thoracic Surgery, a member of the Zumbro Valley Medical Society and the American Medical Association and an Associate and 50 Club Member of the Minnesota State Medical Association.

Dr. Harrington is survived by his wife, Gertrude.

CHARLES J. HEDLUND, M.D.

Dr. Charles J. Hedlund, 63, of Tucson, Arizona, formerly of St. Paul, died February 15. A native of North Dakota and a graduate of the Washington University Medical School in St. Louis, Missouri, Dr. Hedlund had his hospital training at Ancker Hospital, St. Paul.

He was a member of the Ramsey County Medical Society, the American Medical Association and an Associate Member of the Minnesota State Medical Association.

Dr. Hedlund is survived by his wife, Nancy, and a son, Charles.

Respiratory Assistance in the Newborn

MARTHA BURKE-STRICKLAND, M.D.*

WHEN THE RESPIRATORY system cannot cope with carbon dioxide produced in the body and cannot oxygenate the blood sufficiently to support aerobic metabolism needs of the body, hypoxia and hypercarbia develop and pulmonary insufficiency is said to exist. The sudden occurrence of severe hypoxia and hypercarbia is a true emergency which requires immediate assistance.^{1,2} The kind of assistance given depends on the reason for the respiratory failure and the degree of impairment present.

Although accurate assessment of alveolar ventilation requires measurement of blood pH, $p\text{CO}_2$ and $p\text{O}_2$,¹ a gross measure of pulmonary insufficiency may be obtained from the degree of cyanosis, tachypnea, retracting, grunting and lethargy. Relief of these signs is a rough measure of the effectiveness of assistance.

Respiratory Distress Syndrome (RDS) is a common cause of respiratory insufficiency in the newborn.³⁻⁶ Because of the variability in severity of respiratory insufficiency exhibited from case to case as well as the variability from hour to hour in any patient with RDS the physician must be prepared to offer several different kinds of treatment. This is a presentation of the criteria and

techniques used to treat RDS respiratory insufficiency at the Hennepin County General Hospital (HCGH).

Bag Assistance

In mild to moderate RDS, the infant will have characteristic tachypnea, seesaw respirations and some retracting. Reticulogranular pattern and air bronchograms extending beyond the hilar parenchyma are present on chest Xray but the heart silhouette is still clearly discernible.^{3,6,7} The cyanosis is relieved by increasing the ambient oxygen up to 40%. The blood pH may reflect a mild metabolic acidosis in the range of 7.27-7.37, a normal to slightly high $p\text{CO}_2$ at 40-45 mm Hg. The $p\text{O}_2$ will be in an acceptable range between 40-100 mm Hg since the ambient oxygen has been increased to relieve cyanosis. Intermittent short apneic episodes with some increased hypercarbia and hypoxia on the second or third day may signal tiring of the infant. Intermittent bagging with a hand resuscitator and mask may be all the extra assistance that is needed. The length of time and frequency of the bagging is determined by the response of the baby. Usually five minutes every 30-40 minutes is our starting point. If the color remains good and no more apnea occurs, this schedule is maintained. Blood pH and gas

*Director of Newborn Services, Hennepin County General Hospital, Minneapolis, Minnesota.
See editorial, page 409.

Fig. 1—Continuous Positive Airway Pressure (CPAP).

analysis before and after the bagging at least every four hours helps to determine the continuing need and the effectiveness of the assistance. The interval between baggings is lengthened if all values are normal before the bagging cycle is started. It is shortened if apnea or duskiness appear before time for the next scheduled period of assistance. If the baby is immediately dusky or apneic as soon as the bagging is stopped, or, if greater than 40% ambient oxygen is required to relieve the cyanosis, then continuous positive airway pressure (CPAP) should be instituted (Figure 1).

CPAP Technique

We are using the CPAP system described by Gregory, et al.⁸ The baby is intubated with a three mm endotracheal tube that will admit a #8F suction catheter. The endotracheal (ET) tube adapter is connected to an assembly which includes a Norman elbow, a Sommers "T" piece, an eight by 10" length of flexible anesthesia hose, a 500 cc pediatric anesthesia bag, a safety pressure relief valve and a pressure manometer. A controlled mixture of oxygen and air is delivered from a gas blender through a heated humidification chamber (set at 99°F) through a line to the Norman elbow. A water trap in the line prevents water condensate from drowning the patient.

The system pressure is regulated by a thumb screw pinch clamp on the tail port of the anesthesia bag. The system pressure is recorded by the manometer in the line from the Sommers "T" piece. This line also includes the safety pressure relief. The "T" tube in the line is submerged in water to a depth equal to the maximum number cm water pressure desired. A 30 cm setting is standard in our unit.

Removal of exhaled CO₂ from the system depends on wash out by flow of gas. The liter flow should be at least 2½ times the minute volume of the infant. Five liters per minute will handle the problem for most newborns.

A system pressure or end expiratory pressure of 10 cms is arbitrarily set as the beginning pressure and later readjusted according to the infant's response. If little or no improvement is shown, the pressure is increased up to a maximum setting of 17 cms water. If the infant improves, the oxygen concentration is decreased in 5% steps down to 40% or less. Then the pressure is decreased 1-2 mm at a time. The blood pH and gases are determined within 30 minutes after each

change. Changes are made at two hour interval as tolerated.

If the infant suddenly deteriorates, the setting are immediately restored to the point where he previously seemed stable. "Tolerance" is assessed by continued good color, respiratory drive and responsiveness of the infant with a stable pH of 7.25 or more, arterial pO₂ between 40 and 100 mm Hg and a pCO₂ of less than 70. If the pO₂ is marginal at 40, no decrease changes are made until the pO₂ moves toward the higher side of normal.

Frequent monitoring of blood gases and pH are essential to satisfactory assessment and management of this type of care. If these diagnostic services as well as knowledgeable nursing care are not available on a 24 hour basis, then the baby who needs more than 40% oxygen to relieve the cyanosis of his RDS should be transferred to a center that has such facilities.

Rationale of CPAP

CPAP helps the grunting hypoxic infant by substituting the system pressure for the grunting pressure of the baby. He still uses his own respiratory drive and does his own breathing, but the work of breathing is reduced. Areas of lung that were atelectatic and underventilated become expanded and have improved ventilation. By improving the distribution of ventilation to perfusion, the pO₂ will increase.⁸ With more alveoli being ventilated with less energy expenditure there is less CO₂ production, better oxygenation and a readjustment of the pH toward normal.^{1,8}

Any existing metabolic acidosis should be corrected with bicarbonate therapy. The improvement in oxygenation will minimize further generation of metabolic hydrogen ions.

A rapid reduction in ambient oxygen necessary to maintain the baby usually occurs within hours after CPAP is started.⁸ This obviously reduces the risk of Bronchopulmonary Dysplasia (BPD).

When CPAP is Not Enough

There are circumstances when CPAP is not enough. When the lung parenchyma becomes badly involved, the compliance is greatly reduced. The inspiratory effort required to fill the lung (over and above the functional residual capacity being maintained by CPAP) may become too much for the infant. In this situation, CPAP is

combined with a respirator. This type of ventilation assistance is known as continuous positive pressure breathing (CPPB).

Rationale of CPPB

In CPPB, the mechanism of help from the end expiratory pressure is the same as with CPAP assistance, the difference is that now the respirator assumes the entire work load of breathing. Again, many more alveoli can be ventilated with each breath than could be with the baby's weak unassisted efforts.

CPPB Technique

Many respirators can be adapted to deliver this kind of ventilation assistance. A modification of the PR-2 special has proven satisfactory in our unit. Instead of the standard manifold, one with a spirometer side arm is used. The positive end expiratory pressure (PEEP) line is attached to the side arm. This system differs from CPAP in that the system pressure is set by submerging the inline tube to the desired depth in water. Since the venturi system of the PR-2 depends on a drop in pressure for cycling, it is necessary to interpose a one-way valve in the respirator hose so the respirator head will not "feel" the back pressure of the PEEP (Figure 2).

This system is extremely effective when properly assembled. It is very sensitive to air leaks and will not hold the end pressure if there is a leak *anywhere*. Another common problem is reversal of the one-way valve. The respirator cycles merrily on but *no* ventilation reaches the baby. This is most likely to occur during the daily

change of all equipment necessary to control infection. If the baby's condition is severe enough to need CPPB, then he cannot tolerate even a few minutes without it. The personnel must be thoroughly conversant with the setup and know how to troubleshoot problems within seconds, not minutes or hours.

Effectiveness of CPPB

Diffusion of gases across a membrane depends on surface area, concentration of the gases on each side of the membrane and characteristics of the membrane including its thickness.¹⁰ It is well known that one of the main factors limiting viability of the human fetus is maturity of lung function. Surface area of the membrane, i.e., the number of functional alveoli present at a given gestational age and thickness of the membrane, i.e., juxtaposition of the capillary to the alveolar surface, do not reach a maturity that will ordinarily be expected to support life until 26-28 weeks gestation.² Even at this gestational age the 800 gram infant has a tough go of it. A 17-week-old fetus has few if any alveoli, only bronchioles, therefore, it seemed reasonable to assume that if CPPB could ventilate such an immature fetus, it could be expected to ventilate almost anything in the lungs. The first Xray taken within minutes after birth showed complete opacification of a 340 gram infant's chest. The blood pH was 6.74, $p\text{CO}_2$ 110 and $p\text{O}_2$ 20 on 100% oxygen. Fifteen minutes after birth 1.5 mEq NaHCO_3 was given by slow push and CPAP with 100% O_2 was initiated. After 30 minutes the values were as follows: pH 6.95, $p\text{CO}_2$ 90 and $p\text{O}_2$ 49. This was

Fig. 2—PR₂ system modified for Continuous Positive Pressure Breathing (CPPB).

improvement in the right direction but still not adequate in circumstances where the infant is really considered salvageable. Significantly, the baby was able to initiate and sustain respirations with CPAP. Ventilation was changed to CPPB. After another 30 minutes, the pH was 7.41, $p\text{CO}_2$ 38 and $p\text{O}_2$ 45. The respirator was turned off because the baby was losing her skin. She was so friable that every area touched became ecchymotic. Within a short period the thin skin would drop away leaving a raw, hemorrhagic surface. At autopsy the lungs were not hemorrhagic in spite of ET tube manipulation and respirator expansion. Microscopic sections of the lung confirmed the state of immaturity as approximately 17 weeks gestation. The "membrane" was quite thick across which the ventilation was forced. It is *not* suggested that a mass effort be made to save 340 gram abortions. This is presented to emphasize the effectiveness of this method of ventilation under very adverse circumstances.

Complications of CPAP and CPPB

Pneumomediastinum and Pneumothorax

There is an increased incidence of pneumomediastinum and pneumothorax in intubated neonates¹¹ though any newborn infant may have spontaneous rupture with extravasation and dissection of gases through the tissues and into pleural spaces.¹² When extra system pressure is added, the risk may be increased. This is particularly true in the very severely involved infant on CPPB when respiring pressures of 40-50 cms of water are used to overcome the poor compliance of the lung. This is always a calculated risk that is taken for the baby since he will surely die without it. When tension pneumothorax is present, it is treated by tube thoracostomy.

Massive Air Embolism

This can occur with IPPB as well as CPPB when high pressures are used. Apparently large amounts of gas are forced into the pulmonary veins and embolize to the heart. This is not related to manipulation of the umbilical catheters with accidental air embolization along this route. Dr. Tooley, et al., reported such a case in 1969.¹³ We have had one case in ten years experience with respirator assistance of severe RDS.

Pulmonary Edema and Heart Failure

According to Gregory, et al., only 20% of the airway pressure is transmitted as intrathoracic pressure. However, it is possible that, as the lung

improves and becomes more compliant, the intrathoracic pressure rises causing a drop in cardiac output.⁸ In our experience, the infant who requires high end pressure and high respiring pressure of CPPB develops signs of cor pulmonale. The cardiac failure usually responds to digitalization. This is discontinued when the infant no longer requires assistance.

Hypercarbia

After application of end expiratory pressure, some relatively normal areas of lung may have higher volume at end-expiration and therefore have less total ventilation. As the lung improves it is possible to cause CO_2 retention unless the end pressure is lowered rapidly as outlined above. In other words, CPAP or CPPB help when the conditions are right to need it; it can be harmful when no longer needed. Continual assessment and readjustment of settings are necessary if a good outcome is to be obtained.

Bronchopulmonary Dysplasia (BPD)

Bronchopulmonary dysplasia can occur with CPAP and CPPB though the risks have been minimized compared to therapy without CPAP or CPPB. This is thought to be a complication of oxygen therapy, however, some believe that it is a combination of oxygen, intubation and respirator therapy.^{7,14,16} It is our impression that it is oxygen toxicity superimposed upon any underlying lung pathology.

The longer the tracheobronchial mucosa is subjected to an ambient O_2 as high as 80%, the more likely the development of bronchopulmonary dysplasia.^{7,14,15} Studies at HCGH have shown that effects of oxygen toxicity are often apparent after 20 hours of such therapy and invariably present after 30 hours of exposure to high ambient oxygen.^{7,15} If the infant can be sustained through the emergency, the lungs should be able to repair in most instances.^{14,17,18} Criteria are not yet available to determine when toxicity damage is irreversible, therefore, management of respiratory distress should try to minimize the risk from BPD as much as possible.

The cases with the most severely damaged lungs are the ones that require CPPB and are therefore, most vulnerable to severe BPD. Management of BPD includes control of cor pulmonale, prevention of chronic low grade hypoxia and attention to bronchial toilet. The infant may require low ambient oxygen (25-30%) for six to

eight weeks until the lungs gradually improve. The metaplastic process involves the mucous glands as well as loss of the normal ciliated columnar epithelium lining the trachea and bronchi. Excessively viscid secretions in the trachea and bronchi are poorly handled. A high humidity environment, intermittent nebulization, postural drainage and chest thumping are used to facilitate removal of secretions and maintain bronchial toilet.

Infection

Prolonged invasion of a body orifice may predispose to infection. The use of CPAP and CPPB seems to reduce the length of time that intubation is required, however, any use of the endotracheal tube in a lung that is already compromised may be complicated by infection. Scrupulous hand-washing care, good suctioning technique and changing of inhalation equipment daily with gas sterilization of equipment between uses has reduced bacterial complications in our unit. Daily cultures are made of tracheal aspirates. Appropriate antibiotic therapy is started if positive cultures correlate with deteriorating change in the infant's condition.

The incidence of systemic candidiasis has been sharply reduced in our unit by using prophylactic nystatin in the baby's mouth 100,000 units every six hours. It is conjectured that placement of the orotracheal tube interferes with the normal mechanical cleansing action of the tongue movements and the process of swallowing. This increases the chances for seeding the oral mucosa with ubiquitous candida. A debilitated infant is more vulnerable to systemic invasion by the organism from this focal point. Prevention has

proven more satisfactory than salvage after systemic candida has been documented.

Intermittent Positive Pressure Breathing

Intermittent Positive Pressure Breathing (IPPB) still has a place in our spectrum of support for the respiratory failure of the newborn. When the causes for failure are extrapulmonary, for example in drug depression, it is easy to over ventilate the normal lung. In these cases there is no need for CPPB, in fact it may decrease ventilation as described above and CPAP cannot be used without normal respiratory drive. IPPB serves these patients very well.

Since it is an easier mechanism to transport than CPPB, it can also be used for emergency care during transfer of a sick infant. Some units are using the CPAP and CPPB without the safety relief valve. This improves the portability of these systems but may also account for the increased incidence of pneumothorax that has been informally reported through personal communications.

Summary

Varying degrees of respiratory insufficiency in the newborn are exemplified by the variability found in RDS. Respiratory support ranges from increased ambient oxygen in very mild cases through continuous positive pressure breathing in the most severe. In each situation frequent monitoring and knowledgeable nursing care are required for a good outcome. With the newer methods of assistance (CPAP and CPPB) it is possible to salvage intact individuals with fewer long term pulmonary sequelae.

The People Problem

At one of the many meetings last year of the Minnesota State Medical Association's Subcommittee on Alcoholism and Drug Abuse, Dr. Allan Y. Cohen, a guest from the John F. Kennedy University, Berkeley, pointed out the common tendency to consider that there is something terribly wrong, either psychologically or morally, with the drug abuser. That notion often results in a philosophy of social intervention which is reactive and negative. Cohen argues for the use instead of what he calls the "Alternatives Model." He emphasizes the following seven principles:

1. People use drugs because they want to.
2. People use drugs to feel better or to "get high," or they experiment in using drugs out of curiosity or in the hope that they will feel better.
3. People have been and are currently being taught by the media and by broad cultural example that drugs *do* make them feel better.
4. "Feeling better" encompasses a wide range of change in mood or consciousness.
5. While people may well for a time feel better with the use of many mind-altering or mood-altering drugs, drugs may have substantial disadvantages.
6. Generally, people do not stop using drugs until or unless they discover—or are shown—something better.
7. The "key," then, to dealing with people who are abusing or misusing drugs is to focus on the "something better" and, as Dr. Cohen puts it, to "maximize opportunities for experiencing satisfying non-chemical alternatives."¹

He has a lot to say about specific applications of this "Alternatives Model," and those applications are many. To consider just one: it is rather widely accepted that our schools may, through rigidity, inappropriate priorities and irrelevance, themselves contribute to the dissatisfactions which lead children to use mind-altering or mood-altering drugs. Schools may be good at transmitting facts, but poor in helping the student to develop an appropriate "art of living." Cohen points out that one reason for this may be that, while most schools offer courses in such things as music, art, drama, family life education, manual training and physical education, they use in those courses an arbitrary grading scheme which brings to them the same anxieties and destructive feelings of competition which the student finds in the so-called "intellective" courses. He suggests that abolition of grades in such "alternative" subjects might be a significant help in turning youngsters onto a natural "high."

Grade-conscious parents should note that young people as well as older people tend to be attracted to the comfortable and repulsed by the uncomfortable. An "F," or even the threat of an "F," is clearly uncomfortable, and there seems little need for that kind of discomfort in areas of activity which just might get young people so deeply and enthusiastically involved that drugs would not seem comparably inviting.

This seems to make a lot of sense, with its emphasis on the person. No drug is a problem until or unless someone uses it. The "drug problem" is really a "people problem."

*GARAMYCIN Injectable is effective against susceptible strains of the pathogens indicated

Highly appropriate spectrum for today's problem pathogens

GARAMYCIN Injectable offers a high probability of effectiveness against susceptible strains of seven out of seven major gram-negative pathogens. These are:

Escherichia coli
Proteus, indole-negative
Proteus, indole-positive
Pseudomonas aeruginosa
Klebsiella
Enterobacter } species
Serratia

GARAMYCIN Injectable has also been shown effective in serious staphylococcal infection. It may be considered in those infections where penicillins or other less potentially toxic drugs are contraindicated and bacterial susceptibility testing and clinical judgment indicate its use.

serious gram-negative infections (pneumonia, urinary tract infections, septicemia, and wound infections)*
 *susceptible organisms

Start with Garamycin

■ Broad gram-negative spectrum

Because of its broad gram-negative spectrum and its well-established clinical efficacy, GARAMYCIN Injectable can be considered for initial therapy in suspected as well as documented gram-negative sepsis.

Stay with Garamycin

■ Susceptibility of causative organisms confirmed

The results of susceptibility tests will, in most cases, demonstrate the causative organisms' sensitivity to GARAMYCIN Injectable. However, the decision to continue therapy with this drug should also be based on the severity of the infection and the important additional concepts contained in the Warning Box.

■ Relatively low incidence of adverse reactions

Risk of toxic reactions is low in patients with normal renal function who do not receive GARAMYCIN Injectable at higher doses or for longer periods of time than recommended.

■ Bacterial resistance has not been a problem

In the laboratory, resistance has been demonstrated to develop slowly in stepwise fashion. No one-step mutations to high resistance have been reported to date.

40 mg. per cc.

Each cc. contains gentamicin sulfate equivalent to 40 mg. gentamicin

WARNING

Patients treated with GARAMYCIN Injectable should be under close clinical observation because of the potential toxicity associated with the use of this drug. Ototoxicity, both vestibular and auditory, can occur in patients, primarily those with pre-existing renal impairment, treated with GARAMYCIN Injectable, usually in longer periods or with higher doses than recommended.

GARAMYCIN Injectable is potentially nephrotoxic, and this should be kept in mind when it is used in patients with pre-existing renal impairment.

Monitoring of renal and eighth nerve function is recommended during therapy of patients with known impairment of renal function. This testing is also recommended in patients with normal renal function at the onset of therapy who develop evidence of nitrogen retention (increasing BUN, NPN, creatinine or oliguria). Evidence of ototoxicity requires dosage adjustments

or discontinuance of the drug.

In event of overdose or toxic reactions, peritoneal dialysis or hemodialysis will aid in removal of gentamicin from the blood.

Serum concentrations should be monitored when feasible and prolonged concentrations above 12 mcg./ml. should be avoided.

Concurrent use of other neurotoxic and/or nephrotoxic drugs, particularly streptomycin, neomycin, kanamycin, cephaloridine, viomycin, polymyxin B, and polymyxin E (colistin), should be avoided.

The concurrent use of gentamicin with potent diuretics should be avoided, since certain diuretics by themselves may cause ototoxicity. In addition, when administered intravenously, diuretics may cause a rise in gentamicin serum level and potentiate neurotoxicity.

USAGE IN PREGNANCY Safety for use in pregnancy has not been established.

On all in-patient services...
in hospital-acquired gram-negative infections*

For Parenteral Administration

WARNING

Patients treated with GARAMYCIN Injectable should be under close clinical observation because of the potential toxicity associated with the use of this drug.

Ototoxicity, both vestibular and auditory, can occur in patients, primarily those with pre-existing renal damage, treated with GARAMYCIN Injectable, usually for longer periods or with higher doses than recommended.

GARAMYCIN Injectable is potentially nephrotoxic, and this should be kept in mind when it is used in patients with pre-existing renal impairment.

Monitoring of renal and eighth nerve function is recommended during therapy of patients with known impairment of renal function. This testing is also recommended in patients with normal renal function at onset of therapy who develop evidence of nitrogen retention (increasing BUN, NPN, creatinine or oliguria). Evidence of ototoxicity requires dosage adjustments or discontinuance of the drug.

In event of overdose or toxic reactions, peritoneal dialysis or hemodialysis will aid in removal of gentamicin from the blood.

Serum concentrations should be monitored when feasible and prolonged concentrations above 12 mcg./ml. should be avoided.

Concurrent use of other neurotoxic and/or nephrotoxic drugs, particularly streptomycin, neomycin, kanamycin, cephaloridine, viomycin, polymyxin B, and polymyxin E (colistin), should be avoided.

The concurrent use of gentamicin with potent diuretics should be avoided, since certain diuretics by themselves may cause ototoxicity. In addition, when administered intravenously, diuretics may cause a rise in gentamicin serum level and potentiate neurotoxicity.

USAGE IN PREGNANCY Safety for use in pregnancy has not been established.

INDICATIONS GARAMYCIN Injectable is indicated, with due regard for relative toxicity of antibiotics, in the treatment of serious infections caused by susceptible strains of the following microorganisms:

Pseudomonas aeruginosa, **Proteus** species (indole-positive and indole-negative), **Escherichia coli** and **Klebsiella-Enterobacter-Serratia** species.

Clinical studies have shown GARAMYCIN Injectable to be effective in septicemia and serious infections of the central nervous system (meningitis), urinary tract, respiratory tract, gastrointestinal tract, skin and soft tissue (including burns).

Bacteriologic tests to determine the causative organisms and their susceptibility to gentamicin should be performed.

Bacterial resistance to gentamicin develops slowly in stepwise fashion; there have been no one-step mutations to high resistance.

In suspected or documented gram-negative sepsis, GARAMYCIN may be considered as initial therapy. The decision to continue therapy with this drug should be based on the results of susceptibility tests, the severity of the infection, and the important additional concepts contained in the Warning Box. In the neonate with suspected sepsis or staphylococcal pneumonia, a penicillin type drug is usually indicated as concomitant antimicrobial therapy.

GARAMYCIN Injectable has been shown to be effective in serious staphylococcal infections. It may be considered in those infections when penicillins or other less potentially toxic drugs are contraindicated and bacterial susceptibility testing and clinical judgment indicate its use.

CONTRAINDICATIONS A history of hypersensitivity to gentamicin is a contraindication to its use.

WARNINGS See Warning Box.

PRECAUTIONS Neuromuscular blockade and respiratory paralysis have been reported in the cat receiving high doses (40 mg./kg.) of gentamicin. The possibility of these phenomena occurring in man should be considered if gentamicin is administered to patients receiving neuromuscular blocking agents such as succinylcholine and tubocurarine.

Treatment with gentamicin may result in overgrowth of nonsusceptible organisms. If this occurs, appropriate therapy is indicated.

ADVERSE REACTIONS

Nephrotoxicity: Adverse renal effects, as demonstrated by rising BUN, NPN, serum creatinine and oliguria, have been reported. They occur more frequently in patients with a history of renal impairment treated with larger than recommended dosage.

Neurotoxicity: Adverse effects on both vestibular and auditory branches of the eighth nerve have been reported in patients on high dosage and/or prolonged therapy. Symptoms include dizziness, vertigo, tinnitus, roaring in the ears and hearing loss. Numbness, skin tingling, muscle twitching, and convulsions have also been reported.

Note: The risk of toxic reactions is low in patients with normal renal function who do not receive GARAMYCIN Injectable at higher doses or for longer periods of time than recommended.

Other reported adverse reactions, possibly related to gentamicin, include increased serum transaminase (SGOT, SGPT), increased serum bilirubin, transient hepatomegaly, decreased serum calcium; splenomegaly, anemia, increased and decreased reticulocyte counts, granulocytopenia, thrombocytopenia, purpura; fever, rash, itching, urticaria, generalized burning, joint pain, laryngeal edema; nausea, vomiting, headache, increased salivation, lethargy and decreased appetite, weight loss, pulmonary fibrosis, hypotension and hypertension.

DOSAGE AND ADMINISTRATION

GARAMYCIN Injectable may be given intramuscularly or intravenously.

For Intramuscular Administration:

PATIENTS WITH NORMAL RENAL FUNCTION*

Adults: The recommended dosage for GARAMYCIN Injectable for patients with serious infections and normal renal function is 3 mg./kg./day, administered in three equal doses every 8 hours.

For patients weighing over 60 kg. (132 lb.), the usual dosage is 80 mg. (2 cc.) three times daily. For patients weighing 60 kg. (132 lb.) or less, the

usual dose is 60 mg. (1.5 cc.) three times daily.

In patients with life-threatening infections, dosages up to 5 mg./kg./day may be administered in three or four equal doses. This dosage should be reduced to 3 mg./kg./day as soon as clinically indicated.

*In children and infants, the newborn, and patients with impaired renal function, dosage must be adjusted in accordance with instructions set forth in the Package Insert.

For Intravenous Administration:

The intravenous administration of GARAMYCIN Injectable is recommended in those circumstances when the intramuscular route is not feasible (e.g., patients in shock, with hematologic disorders, with severe burns, or with reduced muscle mass).

For intravenous administration, in adults, a single dose of GARAMYCIN Injectable may be diluted in 100 or 200 cc. of sterile normal saline or in a sterile solution of dextrose 5% in water; in infants and children, the volume of diluent should be less. The concentration of gentamicin in solution, in both instances should normally not exceed 1 mg./cc. (0.1%). The solution is infused over a period of 1 to 2 hours.

The recommended dose for intravenous administration is identical to that recommended for intramuscular use.

GARAMYCIN Injectable should not be physically pre-mixed with other drugs, but should be administered separately in accordance with the recommended route of administration and dosage schedule.

HOW SUPPLIED GARAMYCIN Injectable, 40 mg. per cc., 2 cc. multiple-dose vials for parenteral administration.

Also available, GARAMYCIN Pediatric Injectable 10 mg. per cc., 2 cc. multiple-dose vials for parenteral administration.

APRIL, 19

Rehabilitation after Myocardial Infarction

JOHN W. ANDERSON, M.D.*

DURING THE past three years all Blue Earth United Hospital patients suspected of having an acute myocardial infarction were admitted immediately to the intensive coronary care unit (ICCU). The details of this unit have been described elsewhere.⁴ Patients were encouraged to engage in all forms of tolerable activity, the only restrictions being those compelled by a continuous intravenous pathway and the attachments of a cardiac monitoring cable. Self care, use of the bedside commode and bathroom, meals in the chair instead of bed, and frequent walks around the room and into the adjoining hall were the rule. Patients were transferred out of the ICCU when they no longer displayed risk of significant dysrhythmias and were ambulatory without significant chest pain or dyspnea. The average length of ICCU stay was five days, the longest was 13 days.

Selected literature was given to the patients to educate them regarding their coronary artery disease, with particular emphasis on the importance of diet, recreational exercise and avoidance of emotional tension and smoking. Sessions were arranged between the patient, his family and the dietitian. After transfer out of the ICCU the patients were rapidly returned to full activity by daily increases in the frequency, and duration of their walks in the hospital halls, with chest pain being the chief limiting factor. The goal was to have the patients walking outside the building for brief strolls before discharge. The average length of hospital stay for the patients was 15.3 days.

After discharge patients were instructed to engage in daily increases in their walking out-of-doors and were encouraged to walk slightly beyond the onset of chest pain. They were advised to buy pedometers to record their walking distances

to encourage and document their progress. Golfing, hunting and fishing were encouraged. Early return to their gainful employment was advocated. Travel of all types and to all places was advised if such travel allowed continuation of their daily recreational exercise programs.^{5,6,7,8}

Various medications to include digitalis, propranolol, anticoagulants, anti-hyperlipidemics, anti-hypertensives, diuretics, etc. were, of course, employed as indicated, but in most instances it was made clear to the patients that these measures were of secondary value as compared to the importance of diet, recreational exercise, emotional relaxation and cessation of smoking.

All patients were followed by regular out-patient visits and advised to submit to annual comprehensive medical re-evaluation. Stress-testing, employing the bicycle exerciser, was used in some instances.

Some patients did not show improvement in their cardiac function with this program and were referred for evaluation regarding coronary angiography and possible coronary artery surgery. Three patients have had surgery. All are alive.

The majority of patients managed in this way improved rapidly, often dramatically. They frequently became much more tolerant of exercise and experienced less and sometimes no angina as compared to their pre-infarction period. There was usually a general increase in their sense of well-being.

The Study

All patients with a final diagnosis of acute myocardial infarction at the United Hospital of Blue Earth, Minnesota during 1968, 1969 and 1970 were reviewed as of June 30, 1971. Patients in the study had been followed from six months to three and a half years, the average length of follow-up being two years. The diagnostic criteria for a myocardial infarction were: (1) a history of typical pain (2) sequential changes in the electrocardiogram, and (3) a changing elevation of at least

*General staff of the United Hospital, Blue Earth, Minnesota and Assistant Clinical Professor, Department of Family Practice, University of Minnesota Medical School.

Read at the annual meeting of the Southern Minnesota Medical Association on September 18, 1971.

CORONARY CARE

TABLE
Deaths in 103 Acute Myocardial Infarctions

	No. of Cases	Deaths In Unit	Deaths In Hosp. Out of Unit	Total Alive At Disch.	Deaths After Disch.	Total Alive 6-30-71	Total Deaths 6-30-71
1968	33	4	2	27	4	23	10
1969	33	4	2	27	7	20	13
1970	37	3	1	33	3	30	7
Totals	103	11	5	87	14	73	30

one of three serum enzymes: CPK, SGOT and LDH. It was found that a total of 103 cases of acute myocardial infarction by these criteria were admitted to the hospital during the three-year period. Eighty-six with probable infarction were admitted in the same three year period but did not meet the criteria and were excluded from this study. The author was either the attending or consulting physician for all cases. No patients were lost to follow-up.

Results

Seventy-three of the 103 patients diagnosed acute myocardial infarction were alive June 30,

1971, a 70% two-year average survival (Table

Of the 30 deaths 16 occurred during hospitalization for the acute infarction, 11 in the ICU and five after transfer out of the ICU. Eighty-seven of the 103 patients were discharged from the hospital alive and these patients have experienced an 84% two-year average survival since their discharge.

Of those patients who expired after discharge the earliest death was after one week and the latest was after 27 months with the average interval between infarction and death being eight months.

As *Sickness* is the greatest misery, so the greatest misery of sickness, is *solitude*; when the infectiousness of the disease deters them who should assist, from coming. Even the *Physician* dares scarce come. . . . It is an *excuse* to them that are *great*, and pretend, and yet are loth to come; it is an *inhibition* to those who would truly come, because they may be made instruments, and pestilential to the infection of others, by their coming. And it is an *Outlawry*, and *Excommunication* upon the *Patient*, and separates him from all offices not only of *Civility*, but of working *Charity*. A long sickness will weary friends at last, but a pestilential sickness averts them from the beginning.*

When are medical modules the best building method?

When doctors need a high-quality, well-designed Erdman medical building in a short time at an economical price.

Like doctors at the Marshfield clinic in Wisconsin who need space now while we're designing a new 200 doctor facility for them. Or the two GP's in Clarksville, Tennessee, whose space and budget requirements fit an Erdman modular perfectly. Or a hospital out-patient clinic in Gaylord, Michigan. Or the new family practice residency clinic at the University of Minnesota. A modular emergency center in Colorado ski country. A free-standing addition to a clinic in Georgia. The satellite clinic in West Virginia pictured here. We've recently installed these and many more to meet particular needs.

Such as a need more immediate than conventional construction methods can meet. Or simply when the Erdman modular system provides the most practical building for your practice. It's a system which begins in the Erdman factory where modules are built of the same basic design and quality as the medical facilities which we've been building for more than 20 years. For over 6,000 doctors.

Quality. Versatility. Economy. Speed of construction. All are part of the Erdman modular system. By design.

Book Reviews

BLOOD DISEASES OF INFANCY AND CHILDHOOD. Carl H. Smith and Dennis R. Miller. 1972. 820 pages. 3rd Edition. \$29.75. C. V. Mosby Company, St. Louis, Missouri.

The "bible of pediatric hematology" has happily been republished in a new edition. Extensively re-written under the auspices of Doctor Smith, it again is an essential book for the hematologist and for those concerned with or interested in the blood problems of the child. Unfortunately, the untimely death of Doctor Smith might have been the undoing of this fine text, but luckily Doctor Miller beautifully completed the editing and final touches to this volume.

The area of pediatric hematology has grown by tremendous strides since the last edition in 1966. The new volume brilliantly reflects this growth in its exhaustive presentation of new materials. Chapters have been re-written with recent research and clinical findings blended with important materials of the second edition. The bibliography has been updated to include references through 1971. Although the text has grown from 742 to 820 pages, it remains easily readable and well indexed.

Newer discussions in areas including sickle cell treatment and physiology, advances in other hemoglobinopathies, 2-3 DPG, leukocyte function and tests of such, and immunotherapy possibilities in leukemia are well done. Updated chapters including leukopenic syndromes, purpuras, jaundice, and blood abnormalities in the infant are excellent. Re-emphasis of areas of normal cellular function, growth, and development are good in the formation of the ground work of hematology.

Areas of deficiency are few and of not major proportion. Undue emphasis on usage of steroids in hemophilia is unproven and lengthy explanation of plasma treatment is outdated. A reference to the value of australia antigen as a diagnostic aid in leukemia is questionable. The book unfortunately continues the legacy of other hematology texts in not providing morphological illustrations for the reader to utilize. Although the illustrations have been increased from 85 to 175, color plates have only gone from one to three (including a picture of measles in leukemia).

The book is excellent once again and is a necessary reference text. The bibliography provides a marvelous jumping off point. The publication will remain a lasting memorial and a just tribute to Doctor Carl H. Smith.

Minneapolis, Minnesota

COMMUNICABLE AND INFECTIOUS DISEASES, seventh edition by Franklin H. Top, Sr. and Paul F. Wehrle. The C. V. Mosby Company, St. Louis, 1972. Price \$35.

The seventh edition of this volume continues in the superb tradition of its predecessors. Paul Wehrle has joined Franklin Top as a co-editor, and they head a list of 57 distinguished contributors. The editors have added

new sections on Cholera, Cryptococcosis, Cytomegalovirus Infections, Exanthema Subitum, Erythema Infectiosum, Herpes Simplex, Larva Migrans and Plaque, bringing the number of chapters to 68. The format of this edition is similar to that of past volumes: several chapters in the first 100 pages dealing with general topics: infection, immunity, epidemiology, prevention and the study of infections followed by an alphabetical parade of individual chapters dealing with specific etiologic agents or clinical infectious entities. Individual chapters are general both complete and readable. The subject matter does not cover the entire spectrum of infectious diseases; for example, there is no coverage of such general topics as bacteremia (septicemia), urinary tract infection, endocarditis, osteomyelitis and other non-communicable infections. If one desires information on communicable infectious entities, then one finds impressive coverage. In that context, such general topics as bacterial pneumonias, acute respiratory infections, meningitis, infectious encephalitis, etc., are well covered. There is comprehensive coverage of the specific single agent etiologic infections such as chicken pox, hepatitis, staphylococcal infections, etc. This book is a pertinent reference to which physicians can turn with confidence, and should be a valuable asset in any library.

THE EXPECTANT FATHER: A PRACTICAL GUIDE 1972. 167 pp. Paperback \$1.95.

by George Schaefer. Harper and Row Second Edition

The only thing in "The Expectant Father" that referred to the father was the title, which suggested that it might be humorous. I found it dead serious and am surprised that it went into a second edition.

It is so long ago that I was a father that even thinking about being one again gives me a nauseous feeling in the belly and a pain in the area that has been misnamed merely because years ago it sat on a donkey and was commanded to get off. I thank thee, nevertheless.

I hope you have not forgotten my specialty—surgery—breast surgery—bilateral; which reminds me of the story about the Quaker who had a valuable milk cow. He was milking her when she swished her dirty tail in his face. He spoke to his cow and said:

"Dinah, thou knowest that I am a righteous Quaker and slow to anger. Swish not thy tail in mine eyes and face."

Dinah understood not a word and swished her tail again.

"Dinah, thou hast always been a faithful and obedient cow, but if thou swishest thy tail in the face of thine owner again, he will have to sell thee to a good doctor and he, I hope thou knowest, will kick the hell out of thee."

Editor Emeritus

Research in Family Medicine

JOHN E. VERBY, M.D.*

SYSTEMATIC INVESTIGATION of family medicine in its infancy in the U.S.A. It is not part of the undergraduate effort in most medical schools. The natural history of common but serious illnesses and the incidence of psychiatric problems in family medicine have never been accurately determined.

Subjects suitable for research include family studies of morbidity and prevention of disease, genetic information on common diseases, health services research of consumers' needs, health and illness behavior, effects of health education on prevention of disease, cost benefit ratios, use of health services by a defined population, behavioral aspects of doctor-patient-family relationships, and followup studies on therapy and educational efforts for patients and health care professionals. These will have to await a more complete development of sophisticated and true documentation of our populations' disease and health data, its storage, retrieval, and evaluation.

The most significant research that must be undertaken immediately is that of finding the most effective and efficient way of re-educating the general population, physicians, and other health professionals to extract and document the information necessary for creatively solving family health problems. I believe that individual health care needs will be based on family needs in the communities where families live, work, and play. If this be true, we have made a serious mistake by diligently working on the biomedical electron microscope style of research in medical education, while ignoring the need for research in effective and efficient health and disease care delivery to the people here and now!!

While we have gone to the moon and studied the mitochondria of the cell, we have not begun to develop ways of modifying human behavior for the benefit of the individual, families and human population. We must do this research and find ways to effectively apply this knowledge.

We have assumed that practicing physicians consistently extract valid information from patients. This is presumptuous. Physicians have not been trained in undergraduate and graduate work that allows them to interview patients efficiently and proficiently to develop techniques and skills that will allow patients to express and project their true feelings. A great majority of the patients coming to physicians' offices at times will deny and hide their true feelings, attitudes, and thoughts from the physician. The development of rapport, confidence, loyalty and trust between patient and doctor is extremely important if there is to be creative problem solving by both the patient and the physician. Many times this involves working with the family, *not* just the patient!

Proper interview techniques demand experience, training, skills, knowledge, and proper attitudes on the part of the physician. Today's physicians have been trained in general biological knowledge leading to the diagnosis of biological diseases. Today's family physician *must* have the appropriate skills, attitudes and knowledge to solve sociological, psychological and cultural problems as well as biological problems. This phase of education has been almost entirely neglected by medical educators both in the undergraduate training program and the graduate training program. Only in the last few years has any concerted effort been made to utilize audiovisual tapes and other equipment to educate student physicians in methods for properly extracting and evolving appropriate information from their patients and families. A great deal of research is essential to improve this most important technique for all clinicians and physicians caring for patients.

What really is the true incidence and natural history of psychological and sociological diseases? I do not think anyone knows this at this time. In view of the extreme mobility of people, centralized documentation of medical information on all citizens of the world becomes almost mandatory. Without proper techniques for collecting and random retrieving this information, the true incidence of biological, psychological, and sociological dis-

*Associate Professor, Department of Family Practice, University of Minnesota Medical School, Minneapolis, Minnesota.
Presented at the International Congress of General Medicine in Vienna, Austria, in September, 1972.

eases may not appear.

A physician should have the ability to interpret non-verbal communications given by patients. Many diagnoses are made on the basis of hesitation—emotional expressions such as crying, laughing, fidgeting, raising of the eyebrow, frowning, etc. These may be much more important than verbal communications in revealing deeper, hidden emotional feelings which may be the cause of the somatic symptoms. The lack of knowledge of the cause thereby prevents a cure. We may then find ourselves with dozens of patients "circling" us and other physicians on a regular monthly basis. Hours of time are spent with patients on a superficial basis, never extracting the information essential to permanent resolution of the symptoms and signs of psychological and biological diseases!

Initial interviews of an hour or more may save time! It may even be therapeutic and eliminate the need for further pharmacological or professional support. This could save time for the physician and patient and reduce costs of health and disease care services.

The rearrangement of medical curriculum for premedical, undergraduate medical, graduate medical students is essential, if we are to produce future capable clinical physicians for our communities. Interview techniques should be taught before history-taking. Speech and communication courses for interpersonal understanding and persuasion should be taken in college before medical school. Comparative religion, philosophy, cultural anthropology, and sociology courses should be part of the premedical training. Graduate training should emphasize continuous comprehensive preventative medicine for ambulatory patients. We need to find the best way of doing this for our residents in training in family practice. Patients with rare and esoteric biologic diseases comprise the bulk of most medical school hospital populations. This is particularly true in state medical schools with rules and regulations allowing only admission of physician-referred patients to the university medical school hospitals.

Our Department of Family Practice and Community Health at the University of Minnesota Medical School, Minneapolis, Minnesota, is utilizing the expertise of a heterogeneous faculty. This includes family physicians, clinical psychologist and psychiatrists, a cultural sociologist-anthropologist, a biostatistician, an ordained minister/mar-

riage counselor, an educational psychologist, clinical pharmacist, and representatives of other major specialties in the medical school at a main university campus.

We are seriously looking at what it takes to extract valid information from people, families and communities. Quantitative analysis for clinical judgment and problem solving, chronobiology, interview techniques, tutorialships in introduction to clinical medicine, medical history taking, tutorialships for physical diagnosis, courses in Behavior of Man, Man in His Community, health hazard appraisal, genetic counseling, zoonosis, are a number of courses essential for the undergraduate students in medical school. They help him develop sensitivity and awareness as to how to go about extracting information for creative problem solving.

In our Model Family Practice Unit at the University of Minnesota Medical School, we have a part-time clinical pharmacist who works with our students. He supports the outpatient and inpatient services of the Department of Family Practice by identifying side effects and toxic effects of single and multiple drug ingestions of patients. We believe this close relationship with the pharmacist will upgrade care to the patient; the same could be true with the dentist, oral dental surgeon and others.

The following are some of the past research efforts of the Department of Family Practice and Community Health, University of Minnesota Medical School that could be utilized by other academic departments of family practice in other universities around the world:

1. To define the body of knowledge encompassed by family practice by a study of current general practice and by an ongoing analysis of the Department Model Family Practice Unit at the University and in other settings.
2. To develop an ongoing program for the education of health workers and patients designed to broaden the base of responsibility and obligations for ongoing health care.
3. To develop a program for self-recording of data collaborating with experts in chronobiology. Patients have been enlisted in this program designed to provide new methods for disease prevention and early detection.
4. To utilize the technique of statistical decision analysis to help define the pathway of medical decision making, and to utilize this tool in the education of all health professionals.

To establish a broad data base through improved documentation and record-keeping in the Model Family Practice Unit for research studies in family practice.

To improve pharmacists', patients', and physicians' cooperation in health care delivery.

7. To help health care professionals improve their ability to listen and communicate with and understand their patients.

These are just a few of the many efforts being put forth by the family practice department at the University of Minnesota Medical School.

Current Techniques in Radiation Therapy— External Beam: Part II

The University of Minnesota will offer its annual course on Radiation Therapy—Radiation Oncology on May 16-18, 1973. The course will be entitled "Current Techniques in Radiation Therapy—External Beam: Part II."

The course is designed primarily for general radiologists, therapeutic radiologists, and residents. It will present practical concepts in radiation treatment utilizing external beam to include techniques in cervix, vagina, endometrium, ovary, and other gynecologic cancers, bladder, prostate, testicle, colo-rectal cancers, non-Hodgkin's lymphomas, and bronchogenic cancer. Also included will be a clinically oriented analysis of the various external beam supervoltage units, their practical applications and relations to basic treatment patterns. There will also be demonstrations of Brachy therapy, applications and a discussion of the practical applications of the computer, and combined chemotherapy and radiation therapy in the treatment of solid tumors in adults.

Fee: \$120.00. Further information may be obtained from the Office of Postgraduate Medical Education, University of Minnesota, Room 205 Nolte Center for Continuing Education, Minneapolis, Minnesota 55455, or by calling (612) 373-8012.

HERE'S WHERE TO BE IN '73

**RADISSON
South**

**Minnesota
State
Medical Association
May 24-25, 1973
Minneapolis, Minnesota**

Minnesota State Medical Association

If You Take the Time—We Have the Place . . .

YOU, AS A DOCTOR, must often feel the need for more than your share of human time and energy, as priorities keep getting out of order, your attempt to meet all the demands made on you. For this, and other reasons, you owe it to yourself to get a piece of the action on May 23, 24, and 25 at the Radisson South, in Minneapolis, when the Minnesota State Medical Association puts it all together for you at the 1973 annual meeting.

RELAX MIND AND MUSCLE in the golf and tennis tournaments on Wednesday, May 23, or lose yourself in the swim, sun and sauna atmosphere of Radisson's Resort World. Dine leisurely in the carefree mood of three excellent restaurants. Then, renewed in mind and spirit, attend the open hearings of the reference committees in the afternoon and evening. This is your opportunity for input to the grass root functions of your professional organization—to have a part in resolutions that go to the House of Delegates for action and possible incorporation into Association policy.

ON MAY 24, YOU STEP into a world of scientific sessions—designed with you in mind—to enrich your knowledge and provide opportunity for questions, discussion, and exchange of opinions.

YOUR PROBLEMS AND YOUR INTERESTS form the nucleus of the planning for the scientific assembly—giving you information applicable to your patients and to your field of health care delivery. Specialties of the session leaders range from cardiovascular diseases and internal medicine to the behavioral sciences.

Your colleagues, planning the scientific program, are giving generously of their time and expertise. Their efforts deserve your support.

WATCH YOUR MAIL FOR YOUR COMPLETE PROGRAM. See what's in store for you. You'll attend presentations in comfortable settings followed by a chance to discuss informally, at lunch, your particular areas of interest with the various session participants. There'll be time for the "pause that refreshes"—to enjoy free Coke or Fresca as you see the exhibits—and "rap" with your colleagues.

ZEROING IN ON YOU AND YOUR NEEDS, "The Personal Life of the Physician" comes into focus as the subject of a session at 3:30 p.m. on Friday, May 25th.

ABORTION PROCEDURES IN THE first and second trimesters will be the topic of talks by Dr. Jane Hodgson of St. Paul and Dr. Robert Goodlin of Stanford University's School of Medicine during the closing sessions on Friday.

OF REAL INTEREST TO YOU are the scientific exhibits which graphically present advancements in techniques, procedures, treatment, and other related developments in medicine.

SHARE THE WEALTH of knowledge the meeting offers with the interns, medical students, nurses, dietitians and technicians you meet in your work-a-day world—encourage them to attend.

HOW CAN ONE MEETING OFFER SO MUCH? You'll find the answer in the Great Halls, East and Center, and the Great Hall Foyer where the "paying" guests present to you their technical exhibits. Their dollars provide financial pillars that help support the whole meeting structure. They underwrite a good share of the expense—and they offer some real help to you on problems ranging from money management to patient management. Your schedule will allow time to talk with the people who've paid to bring their products to you. It's all there in attractive displays, conveniently close to the action.

SOMETHING SPECIAL FROM THE SPECIALTIES is the "Symposium on Trauma" presented May 25th by the Minnesota Chapter of the American College of Surgeons. Plans include a full morning of meetings, discussion, and dialog on treatment of the injured (from initial assessment to the role of nursing care) and a noon business luncheon meeting which features a talk on cancer patients and hospitals by Andrew H. Mayer, M.D., a Fellow of the American College of Surgeons.

THE PHYSIATRIC SOCIETY'S day of recognition for Dr. Miland Knapp takes place on Saturday, May 26, from 8:30 a.m. to 4:30 p.m., with a pleasant break for an enjoyable noon luncheon, at which Dr. Knapp will speak.

ON WEDNESDAY, MAY 23, from 9 a.m. to noon,

ANNUAL MEETING

the faculty from the Department of Family Practice and Community Health at the University Medical School will conduct "An Educational Seminar and Information Exchange for Preceptors of Phase B, Phase D, and the Rural Physician Associate Program."

YOUR WIFE WILL RECEIVE A WARM WELCOME from the ladies of the Woman's Auxiliary. They invite her to join them at the functions of their general membership. If she's not a member, they'd especially like to greet her. The Auxiliary's other-than-business plans include a social hour, luncheon, tea and festive banquet on Thursday evening. Here, the ladies will join their husbands in honor-

ing those physicians who celebrate fifty years as licensed practitioners, the recipient of the Association's Distinguished Service Medal and the President's Plaque and Awards; and they'll welcome the incoming president. Dancing follows in the beautiful garden court.

YOU CAN CURE YOUR PRIORITY ILLS with one capsule of professional seminars; a brief holiday; and time for your wife and family. Write yourself a prescription. Take as directed at the Minnesota State Medical Association's Annual Meeting . . . Radisson South, Minneapolis, May 23, 24, and 25 . . . the place to be in '73.

1973 Schedule of Events

Wednesday, May 23

Credentials Committee, 12:15 p.m., Great Hall Foyer
House of Delegates, First Session, 1 p.m.—Great Hall West
Delegates/Councilors Buffet, 6 p.m.—Tiffany
Reference Committees—Open Hearings, 4 p.m.—Verandas 1, 2, 4, 6, 8
Reconvene 7:30 p.m., Verandas 1, 2, 4, 6, 8
Annual Golf Tournament—Minnesota Valley Country Club
Annual Tennis Tournament—Normandale Tennis and Swim Club
Specialty Group Meetings

Thursday, May 24

Breakfasts—Committee, 7:30
Exhibits Open, 8:30-5:00—Great Hall East, Center, Foyer
Scientific Sessions Begin at 9:00 a.m. and continue throughout day
MSMA Luncheon, 12:30 p.m.
President's Reception, 6 p.m.—Garden Court
Annual Banquet, 7 p.m.—Great Hall West, with dancing following at 9:30 in the Garden Court

ANNUAL MEETING

Scientific Program

1973 Minnesota State Medical Association Annual Meeting

Thursday, May 24

Physiology in Daily Practice

Basic scientists will join with clinical practitioners throughout the day to correlate cellular, organ, and system physiology with the problems met by the doctor in daily practice.

9:00-10:30—The Big Heart

Session Leader: Carlos E. Harrison, Jr., M.D. Arnold L. Brown, Jr., M.D.; George Cooper IV, M.D.; Dieter W. Sack, M.D.

Cardiac pathophysiology and basic mechanisms will be discussed in informal exchange in terms of clinical problems including atrial septal defect, valvular stenosis, and the chronic potassium depletion syndrome of congestive heart failure. Hypertrophy of the heart is a fundamental response to work overload. It may be secondary to excess flow as for example in septal defects or to obstructive valvular disease such as aortic and pulmonary valve stenosis. The external work performed by the heart muscle is one of the major determinants of myocardial oxygen consumption. Changes in ionic fluxes in the organelles of the cardiac cell occur in response to work overload in the heart and in heart failure. Cases exemplifying each of the clinical problems will be presented to illustrate recent advances in clinical non-invasive technics and the discussion will link current concepts of cardiac contraction, energetics, and hypertrophy to these clinical problems.

11:00-12:20—HYPERTENSION 1973: Basis for Rational Management Decisions

Session Leader: Cameron G. Strong, M.D. L. A. Brennan, Jr., M.D.; F. G. Knox, M.D., Ph.D.; R. M. Tucker, M.D.

A physiologist and three clinicians argue that understanding the physiology of hypertension can help the physician make management decisions for his hypertensive patients.

Illustrative case examples will be used to provoke discussion from panel members and audience alike as mechanisms operative in the hypertensive patient are explored. Particular attention will be paid to the best methods of obtaining and interpreting the numbers defining the operative mechanism and suggesting optimal management choices.

This discussion will necessarily involve sodium and potassium handling by the kidney, the renin-angiotensin-aldosterone system, the use of plasma renin activity in the diagnosis of the various subgroups of hypertensive patients, and the physiologic derangements produced by renal insufficiency.

The panel members will attempt to integrate this basic information in formulating management programs for patients with commonly encountered hypertensive problems.

1:40- 3:00—Psychopharmacology and Brain Function

Joint Session Leaders: Faruk S. Abuzzahab, Sr., M.D., Ph.D. and Jack Kelley, M.D.

Recent advances in the neurochemical transmission have helped us evolve a unified understanding of the mechanism of action of psychoactive medications as well as some of their behavioral side effects. The antidepressant, antiparkinson and hallucinogenic drugs are viewed as capable of increasing synaptic transmission, while the antipsychotic, antianxiety and hypnotic agents decrease synaptic transmission in a differential manner. The success of drug applications in the control of the major symptoms of schizophrenic and affective disorders have lent further proof to the theory that there may be a defective neurotransmission as the underlying etiologic factor in these disorders. Some antihypertensive medications (pargyline, methyl dopa, guanethidine) and anesthetics (droperidol, ketamine) also act on the synaptic transmission and might interact with psychoactive medications. The neurotransmitter theory is making inroads in elucidating the neurophysiologic basis of emesis, hostility, libido, memory, rapid eye movement (REM) or dream state and drug withdrawal symptoms. Eventually, this would assist us in developing drugs that could possibly alter these states.

ANNUAL MEETING

Thursday—Continued

3.30- 5:00—Immunology, Infection and Cancer: 1973

Joint Session Leaders: Charles F. McKhann, M.D.; Richard L. Simmons, M.D. and John H. Kersey.

The immune response now appears to have at least two components: cellular immunity and antibody production. Each of these undergoes its own separate route of development and has its own spectrum of specific activities. Often the two systems interact with each other so that the response that we see in the form of antibody production or graft rejection is the result of a combined effort. The immune or "killer" lymphocyte, which is responsible for the rejection of transplanted tissues, develops under the guidance of the thymus and is called a T-lymphocyte. Its counterpart, the B-lymphocyte, is derived from the bone marrow, and is eventually responsible for antibody production. Many antigens induce responses in both systems and some actually require the participation of both systems before an effective immune response is obtained.

There are two interesting interactions between infections and the immune response. The first of these is where the infection itself depresses the immune response and may actually pave the way for super infections that follow. The converse of this is where the immune response is defective, leaving the host vulnerable to a wide range of infections. In addition to the immunologic deficiency diseases, patients undergoing immunosuppression for transplantation or for a variety of other diseases are unusually prone to the development of infections. It is noteworthy that many of these serious infections result from over growth of common organism which the normal individual controls without difficulty.

Tumors also appear to have an intimate interaction with the immune system. Some tumors depress the immune response quite seriously, not only with respect to that specific tumor but in general. Conversely, a wide range of human tumors appear to be antigenic in their own right and capable of specifically stimulating immunity. The paradox is why these tumors grow so successfully in the face of host immunity. Several mechanisms by which the tumor may escape from immune control are not known. Knowledge of the immune interaction that takes place between the patient and his tumor has led to a variety of attempts to manipulate the immune response to increase its effectiveness as a defense mechanism.

Friday, May 25

Daily Practice in Society

Clinical practitioners and behavioral scientists will discuss the problems of practicing medicine in contemporary society.

9:00-12:00—Symposium on Trauma—John F. Perry, M.D.

All specialties, as well as general medicine, will find these topics of interest: (1) Initial Assessment of the Injured Patient—Ernest Ruiz, M.D. and Robert A. van Tyn, M.D. (2) Treatment of Shock in the Injured Patient—Richard C. Lillehei, M.D. and Ronald Dietzman, M.D. (3) Diagnosis of Visceral Injury Following Blunt Abdominal Trauma—Richard G. Strate, M.D. (4) A Protocol for Evaluation of Genito Urinary Injury—Alexander Cass, M.D. and Gerald Ireland, M.D. (5) Anesthesia in Severely Injured Patients—Claude Swayze, M.D. and G. Thomas Wier, M.D. (6) Management of Injuries in Childhood—Arnold Leonard, M.D. (7) Assessment and Early Management of Maxillofacial Injuries—Lawrence Boies, M.D. (8) Fracture Management in the Patient with Multiple Injuries—Thomas Comfort, M.D. (9) Problems in the Nursing Care of Patient with Multiple Injuries—Rita Laska, R.N.

9:00-12:00—Symposium on Trauma—John F. Perry, Jr. M.D.

Session Leader: Donnell D. Etzwiler, M.D.

Health care is undergoing immense changes. Health professionals and patients alike are concerned about the quantity, quality, and cost of such services. Health professionals are currently joining together in forming "teams" capable of providing more and better care at a lower cost. While this approach is an improvement, the most important member of the health care team is all too frequently forgotten—the patient himself.

Effective treatment of chronic diseases or the maintenance of good health can only be achieved with the cooperation of an informed and interested patient.

To prepare patients and members of their families to recognize their role and assume their rightful responsibilities, planned systems of patient education are necessary. The panel of health professionals and consumers will discuss the importance of patient education and involvement as a part of quality health care.

ANNUAL MEETING

Friday—Continued

11:00-12:00—Children in Trouble: The Early Years—Session Leader: Francis S. Wright, M.D.

Early identification and appropriate management could well be the key to problems of the young—many of which a physician may encounter in his own family life. Discussion will investigate developmental problems, behavior disorders, learning difficulty, and the family stress syndromes that come into play in the treatment of children.

1:40- 3:00—Problems of Aging—Session Leader: Floyd K. Garetz, M.D.

Perceptual and Psychological Changes in Aging, Peter R. Peth, M.D.; Inner Life of the Aged, John P. Brantner, M.D.; Gerontological Aspects of Aging, Stafford W. Gedge, M.D.; Common Psychiatric Problems of the Aged, Floyd K. Garetz, M.D. and Medical Management of an Aging Population, Jesse J. Barron, M.D.

Science has added years to human life and produced new problems in gerontology that demand solution and management. The physician needs to seek out ways to help an aging population handle the psychological changes and common psychiatric problems thrust upon it in today's youth-oriented society. As the years add up for his patients, he strives to understand their inner lives and what his medical role will be. This session hopes to stimulate thought and provide some answers to the problems of adding better living to longer lives through medical management.

3:30- 5:00—The Personal Life of the Physician

Joint Session Leaders: John W. LaBree, M.D. and Carl E. Christenson, M.D.

Problem Solving in Clinical Medicine—Laurence A. Savett, M.D.

The "problem oriented system" is a system for clinical problem solving, and a key part of this system is a structured medical record which contains *cumulative* data in an *accessible* format.

The essential part of the system is a problem list. If it is complete and comprehensive, the problem list accrues the following benefits to patient care: (1) provides a means for recalling data which may not be significant when first recorded but which may be significant later on, (2) flags signs and symptoms which demand workup or followup, (3) tends to crystalize clinical relationships which otherwise would not be apparent, and it enables the physician to construct a reasonable differential diagnosis for a new problem. It establishes the "clinical context," (4) guides therapy and (5) provides the framework for professional-to-professional communication. In particular, the nurse can participate to a greater extent in data collection, decision making, and patient teaching, once she is aware of the diagnostic and therapeutic problems.

Specific cases will be presented to illustrate these points.

The Doctor's Image of Himself—C. Dwight Townes, M.D.

Problems come to mind first. There are joys in the personal life of physicians: status; gratification of doing good for people; the depth of understanding for your own and your family's feelings which you can gain from studying and dealing with the feelings of patients; the excitement of dealing with life and death.

What does being a physician do to his or her personal life? It can make many things difficult, but it's not the situation the physician is in that determines this. It's what he does with it. It can drive him to drink, drugs, divorce, and death more than most occupations.

Why? Is it the stress of the job—or the vulnerability of the type of person who goes into medicine?

One great problem for the physician is the apparent requirement to be a god. Is this possible? He knows he has clay feet, but he wonders if he will be destroyed if he shows them. To whom can he go for help?

This session will attempt to grapple with these and other burning questions of the physician's personal life.

Management of a Doctor's Earnings—Gary D. McDowell

The presentation concerns itself with two interrelated topics of equal importance to the physician—management of current income and disposition of net worth.

The first involves the personal management of professional earnings. Primary stress is placed on the four phases of financial planning: audit, plan, implementation, and monitoring. Special emphasis will further be placed upon the avenues of investment available, their tax impact, and the risk reduction elements to be considered.

The second will deal with the family planning and tax considerations inherent in property devolution. Primary emphasis will be placed upon the use of trusts to minimize the impact of federal and state taxes and to provide utmost flexibility for the individual family situation.

ANNUAL MEETING

Friday—Continued

1:40- 2:20—The Medical, Psychological and Social Hazards of the Abortion

Session leader: Fred E. Mecklenburg, M.D.

Several sets of data from current U.S. and world literature on the immediate and long-range morbidity and mortality of induced abortion, including the so-called "latent morbidity" or effect on subsequent pregnancies will be presented.

Specific problems of accurate data collection and how this applies to currently available data from New York and other "liberal" abortion states will be discussed as will the problem of prematurity as an aftereffect of induced abortion with supporting data from Eastern Europe and Japan.

The specific hazards of intrauterine saline abortion causing coagulation defects and maternal hemorrhage and the hazards of interruption of the first pregnancy will be stressed, with supporting data.

Confusing psychiatric data will be reviewed.

2:20- 3:00—Preabortion and Postabortion Counseling

Session Leader: Fred A. Lyon, M.D.

Pre- and postabortion counseling is an integral part of the care a patient receives when considering terminating a pregnancy. The follow-up care is just as significant and important, since it is at this time that any further questions can be answered. It gives the physician the opportunity to reinforce the instructions given at the time the abortion was performed.

At the preabortion counseling session, the patient's fears about her pregnancy are discussed; the alternatives to terminating the pregnancy are elaborated; the techniques of performing the abortion are explained to allay fears and apprehension and the reasons why the patient became pregnant are reviewed, and constructive information and advice is offered. Plans for referral to social service agencies are investigated.

The patient is reassured that her physical health is not impaired. Support is given to allay any fears regarding her emotional health. The concept of pregnancy prevention is again mentioned, and the opportunity is taken to inquire whether birth control is actually being used. (A recent published study shows that 38% of women given contraceptives at the time of abortion are no longer using any protection 12 months later.)

Counseling should be made available to all patients seeking abortions. It should not be compulsory. To deny a patient an abortion because she rejects counseling would be foolhardy. Physicians should acquaint themselves with the current techniques of counseling.

3:30- 5:00—The Abortion Procedure

Joint Session Leaders: P. Theodore Watson, M.D. and Erick Y. Hakanson, M.D.

The First Trimester Abortion—Jane E. Hodgson, M.D.

The conservatively aloof attitudes of the medical profession toward providing abortion and contraceptive services as a part of routine health care have long been apparent. The recent legalization of pregnancy termination by the Supreme Court should greatly help in making these services available to all women. The New York State experience of the past two years has documented the safety of performing first trimester abortions with vacuum aspiration in a non-hospital setting.

The advantages of the free-standing clinic over hospital abortion services are several, with emphasis on accessibility, lowered complication rates, reduced costs, and less patient dehumanization. The experiences of a Washington, D.C. non-profit, tax-exempt, free-standing abortion clinic and the technique and complications of the first trimester abortion with vacuum aspiration are described.

ANNUAL MEETING

Friday—Continued

Mid-Trimester Therapeutic Abortion—Robert C. Goodlin, M.D.

On our service, mid-trimester therapeutic abortions are accomplished with either hysterectomy, hysterotomy or hypertonic saline amnioinfusion. The saline technique is associated with the shortest hospital stay but with the most late complications, while the opposite is true of the hysterectomy technique. Several other mid-trimester abortions techniques have been used (in small numbers of patients) but with less satisfactory results.

The present saline amnioinfusion technique includes: (1) withdrawal of 50 to 200 ml of amniotic fluid, (2) gravity infusion or injection of 200 to 250 ml of 20% saline plus antibiotic, (3) intravenous oxytocin infusion at rates of 50 to 300 mu/min, (4) cervical insertion of laminaria tents or a Foley catheter. Past serious complications include: (1) water intoxication, (2) septicemia, (3) hypofibrinogenia with renal failure, (4) lower segment lacerations with retroperitoneal hematoma and (5) cervical fistuli; but no maternal deaths have occurred.

A problem common to all mid-trimester abortion techniques is associated emotional stress of both hospital staff and patients. Since we are unable by physical examination to estimate gestational length closer than \pm three weeks, an occasional viable size fetus is unintentionally destroyed. Likewise, unlike the patient requesting first trimester abortion, those asking for mid-trimester abortions often are ambivalent over terminating the pregnancy and in my experience, frequently express feelings of guilt or hostility after the procedure.

ATTEND YOUR ANNUAL MEETING!!!

May 24-25, 1973

Radisson South :- Minneapolis

Classified Advertisements

Classified advertising rates are thirty (30) cents a word; minimum monthly charge \$7.50; key number, fifty (50) cents additional.

Replies to advertisements with key numbers should be mailed in care of Minnesota Medicine, 375 Jackson, St. Paul, Minn. 55101.

FOR SALE—Fully equipped office (nurse and receptionist) in Tracy, Minn. May move right in to a busy lucrative practice. For complete details, R. O. Schroepel, M.D., Tracy, Minn. 507-629-4211.

SOUTHWEST MINN. HEALTH CARE ENTERPRISE—Six communities working together to recruit physicians to implement model rural health care program designed by and affiliated with Univ. of Minnesota, Dept. of Family Practice. New clinic available, estimated 15,000 in model area, 3 nursing homes, plus other normal attributes of top rural farming area. Contact: Wallace W. Nelson, Lamberton, Minn. 56152. Tele: 507-752-7372.

YOUNG family practitioner(s) wanted. Three doctor clinic built 1973 by 30 year old doctor. New hospital in town. 35 miles south Minneapolis. Early partnership. Salary plus incentive bonus. John Berg, M.D., New Prague, Minnesota 56071.

SHELL LAKE CLINIC, LTD., Shell Lake, Wisconsin, expanding to seven man group. Three family physicians and one surgeon desire additional two family physicians and one internist. New 70 bed general hospital adjoins clinic. Excellent remuneration in corporate practice. City surrounds one of largest and finest swimming and fishing lakes in Northwest Wisconsin. Call 715-468-2711 or write to Clinic Manager Darrell Bailey.

G.P. OR INTERNIST. 40 hour week, no night calls, mainly examining executive and professional people. Easily arranged vacation time or time for varied pursuits. Must be 60 or below, but special provision can be made for orthopedic, cardiac or respiratory impairments. \$30,000 base. Write MINNESOTA MEDICINE—479, 375 Jackson, St. Paul 55101.

GENERAL PRACTITIONER needed as associate in county seat community of 2,000. Modern 35 bed hospital 4 blocks from fully equipped clinic. An excellent opportunity to live the good life in rural Minnesota. Write: Minnesota Medicine-477, 375 Jackson St., St. Paul 55101.

A BETTER PLACE TO PRACTICE MEDICINE. For those who would prefer to live in a warmer climate, avoid the big city school, traffic and practice problems; contact this multi-specialty group, located in a city of 100,000 people in North Central Texas. Specialists in Internal Medicine, Family Practice, Pediatrics, General and Orthopedic Surgery are needed to complement the current

staff of twenty-one full time physicians. Wichita Falls Clinic-Hospital, 1300 Eighth, Wichita Falls, Texas 76301.

ASSOCIATE FOR AAFP member in professional corporation or expense and call sharing association. New clinic building in construction to serve three rural communities. Immediate partnership in corporation, if desired. All corporate benefits immediately. Located in beautiful Hiawatha Valley of southeastern Minnesota, 35 miles from Mayo Clinic and 55 miles from Gunderson Clinic. Contact: R. L. Sauer, M.D., Root River Valley Medical Clinic LTD., Box 496, Preston, Minnesota 55966.

ASSOCIATES WANTED: Family doctors to join growing Family Practice Department in a large multiple specialty medical center, Minneapolis suburb. Excellent opportunity for teaching undergraduate and graduate students in Family Practice. Four man department with excellent growth potential. Reply to Dr. Harley J. Racer, Chairman, Family Practice Department, St. Louis Park Medical Center, St. Louis Park, MN 55416. Telephone 612-927-3320.

RADIOLOGIST, PATHOLOGIST, GENERAL SURGEON AND PEDIATRICIAN—For a 12 man group, desirable lake area of Minn. 50 miles from Fargo-Moorhead. Boat-swim-fish-hunt-ski-golf. Partnership in 1 yr. 100 bed hospital. Write or call collect. (218) 847-5646. J. F. Knapp, M.D. Box 727, Detroit Lakes, Minn. 56501.

FAMILY PHYSICIAN needed to replace member (taking F. P. Teaching position) of five man F.P. group in Robbinsdale, suburb of Mpls., Minn. Active family practice includes medicine, pediatrics, surgery, and OB, utilizing two nearby hospitals. Salary one year, full partnership thereafter. Contact D. D. Metz, M.D., 3819 W. Broadway Mpls., Minn. 55422 (612) 533-2534.

WANTED—Internist—Board qualified or certified for city practice with a group of 2. Good salary. Partnership in future. Write: MINNESOTA MEDICINE—480, 375 Jackson, St. Paul 55101.

CONSIDERING A MOVE from big city practice? Want to settle in the lake-filled country? The Willmar Medical Center is an expanding 23-man multi-specialty group with a real need for additions in the ENT, orthopedic, Ob-GYN, internal medicine and psychiatry specialty fields. Presently moving into large new clinic and hospital facilities. Write J. J. Dillenburg, Administrator, for information packet.

Classified Advertisements

ANESTHESIOLOGIST, young Board eligible, FACA, available for two week locum in August, 1973. Terms negotiable. Solo or supervisory. Write **MINNESOTA MEDICINE**—481, 375 Jackson, St. Paul 55101.

RHEUMATOLOGIST-IMMUNOLOGIST, age 37, board certified in Internal Medicine, now in academics, seeks association. Prefers west Minneapolis and western Hennepin County but will consider other areas. Write: **MINNESOTA MEDICINE**—482, 375 Jackson St., St. Paul 55101.

WANTED TO BUY—Examining tables, wall and base medical cabinets, stools, x-ray equipment, wall mounted blood pressure and eye, ear, nose and throat equipment not over 5 years old. Drs. Roberts and Nafziger, 2912 Hamilton Blvd., Sioux City, Iowa 51104.

EQUIPMENT FOR SALE: 300 MA X-ray, Shield, Pediatric table/scale, Steeline Exam Table, Sterilizer Cabinet, Specialist's Cabinets, suction pressure unit, Operator's Stools, Diapulse, Autoclave, Microthermy, Diathermy, Unimeter, Bantam Bovie, Dictaphone, Suction Pump, Coreco camera. Reasonable. H. C. Winge M.D., 221 Rice Creek Terrace, Fridley, MN 55432, (612) 566-8202.

WAYZATA MEDICAL BUILDING OFFICE SUITES—Located in the fastest growing suburban area in the Twin Cities. We offer:

- Surrounding area of lakes, country clubs, woods, beautiful homes;
- Unsurpassed medical building facilities
- Fast growing area—high median family incomes
- Beautiful building—inside and out
- Inner courtyard with trees and landscaping
- Heated indoor parking
- Adjacent access to freeway system
- Low rental rates—favorable base terms
- Financial services

We have grown to fourteen specialties since our building was completed two years ago. We particularly are interested in Orthopedics, Psychiatry, Urology, Otolaryngology, Internal Medicine and Dentistry. Give us a call. We have a lot more to show you and to talk about. Reply to: Mr. Paske, Wayzata Medical Building, 250 North Central Avenue, Wayzata, Minn. 55391, (612) 473-0031.

POSITION WANTED—GENERAL SURGEON with experience in thoracic and peripheral vascular surgery desires association with multi-specialty or general practice group. Minnesota license and FLEX. Available October, 1973. Board eligible. Write: **MINNESOTA MEDICINE**—483, 375 Jackson St., St. Paul 55101.

American Medical Writers Association

North Center Chapter

Seminar: "To Improve Medical Writing"

Date: May 12, 1973

Time: 9 A.M. - 4:30 P.M.

Place: Rochester, Minnesota
Mayo Building — Mayo Clinic
19th Floor Lecture Hall

Fee: \$25 (includes luncheon)

Registration is limited to 45 persons. The seminar is open to members of the American Medical Writers Association and to all others interested in medical writing and editing.

Please send advance registration and check to: Mrs. Eleonore M. Clappier, Proceedings Office, Mayo Clinic, Rochester, Minnesota 55901, (507) 282-2511, Ext. 2154.

T₄ IS THE PREDICTABLE HORMONE BECAUSE IT LOVES PROTEIN.

SYNTHROID® (sodium levothyroxine) is pure synthetic T₄, the major circulating thyroid hormone. It is reliable to use because of its affinity for protein-binding sites in the blood. T₃ is more fickle. Sometimes it binds. Sometimes it doesn't. T₄ more *predictably* binds to protein.

ALL THYROID-FUNCTION TESTS ARE USEFUL IN MONITORING SYNTHROID THERAPY

No calculations are needed, test interpretation is simple.

Any of the commonly used T₄ thyroid function tests (P.B.I., T₄ By Column, Murphy-Pattee, Free Thyroxine) are useful in monitoring patients on T₄ because they *all* measure T₄. Patients on SYNTHROID are thereby easy to monitor because their results will fall within predictable, elevated test ranges. Of course, clinical assessment is the best criterion of the thyroid status of the drug-treated patient.

TWO GOOD REASONS WHY THE ROAD TO NORMALIZED THYROID STATUS IS SO SMOOTH FOR THE SYNTHROID PATIENT

(1) The onset of action of T₄ is gradual. It has a long in vivo "half-life" of over six days. (Occasional missed doses or accidental double-doses are of no concern because of this fact.) (2) Since SYNTHROID contains only T₄, the potential for metabolic surges traceable to more potent iodides (T₃) is eliminated.

TEST	HYPOTHYROID	SYNTHROID THERAPEUTIC NORMAL
P.B.I.	Less than 4 mcg %	6-10 mcg %
T ₄ By Column	Less than 3 mcg %	7-9 mcg %
T ₃ (Resin)	Less than 25%	27-35%
T ₃ (Red Cell)	Less than 11%	11.5-18%
Free Thyroxine	Less than 0.7 nanograms %	0.7-2.5 nanograms %
Murphy-Pattee	Less than 2.9 mcg %	4-11 mcg %

AS WITH ANY THYROID PREPARATION, CAUTIOUS OBSERVATION OF THE PATIENT DURING THE BEGINNING OF THERAPY WILL ALERT THE PHYSICIAN TO ANY UNTOWARD EFFECTS.

Side effects, when they do occur, are related to excessive dosage. Caution should be exercised in administering the drug to patients with cardiovascular disease. Read the accompanying prescribing information for additional data and write Flint Laboratories.

e synthetic thyroid drugs,
HROID is the most
mical to the patient.

WHY DOES SYNTHROID COST LESS THAN SYNTHETIC DRUGS CONTAINING T_3 ?

Very simple. T_3 costs more to make synthetically than does T_4 . So it is economically necessary for a synthetic thyroid medication containing T_3 to cost more than one containing T_4 alone. Synthetic combinations cost patients nearly 50% more than SYNTHROID³ because the T_3 costs more to start with; also there is the additional expense of formulating a tablet containing two active ingredients.

State _____

Zip _____

Indications: (sodium levothyroxine) is specific replacement therapy for diminished or absent thyroid function resulting from primary or secondary atrophy of the gland, congenital defect, surgery, excessive radiation, or antithyroid drugs. Indications for SYNTHROID (sodium levothyroxine) Tablets include myxedema, hypothyroidism without myxedema, hypothyroidism in pregnancy, pediatric and geriatric hypothyroidism, hypopituitary hypothyroidism, simple (nontoxic) goiter, and reproductive disorders associated with hypothyroidism. SYNTHROID (sodium levothyroxine) for Injection is indicated for intravenous use in myxedematous coma and other thyroid dysfunctions where rapid replacement of the hormone is required. The injection is also indicated for intramuscular use in cases where the oral route is suspect or contraindicated due to existing conditions or to absorption defects, and when a rapid onset of effect is not desired.

Precautions: As with other thyroid preparations, an overdosage may cause diarrhea or cramps, nervousness, tremors, tachycardia, vomiting and continued weight loss. These effects may begin after four or five days or may not become apparent for one to three weeks. Patients receiving the drug should be observed closely for signs of thyrotoxicosis. If indications of overdosage appear, discontinue medication for 2-6 days, then resume at a lower dosage level. In patients with diabetes mellitus, careful observations should be made for changes in insulin or other antidiabetic drug dosage requirements. If hypothyroidism is accompanied by adrenal insufficiency, as Addison's Disease (chronic subcortical insufficiency), Simmonds's Disease (panhypopituitarism) or Cushing's syndrome (hyperadrenalism), these dysfunctions must be corrected prior to and during SYNTHROID (sodium levothyroxine) administration. The drug should be administered with caution to patients with cardiovascular disease; development of chest pains or other aggravations of cardiovascular disease requires a reduction in dosage.

Contraindications: Thyrotoxicosis, acute myocardial infarction. **Side effects:** The effects of SYNTHROID (sodium levothyroxine) therapy are slow in being manifested. Side effects, when they do occur, are secondary to increased rates of body metabolism; sweating, heart palpitations with or without pain, leg cramps, and weight loss. Diarrhea, vomiting, and nervousness have also been observed. Myxedematous patients with heart disease have died from abrupt increases in dosage of thyroid drugs. Careful observation of the patient during the beginning of any thyroid therapy will alert the physician to any untoward effects.

In most cases with side effects, a reduction of dosage followed by a more gradual adjustment upward will result in a more accurate indication of the patient's dosage requirements without the appearance of side effects.

Dosage and Administration: The activity of a 0.1 mg. SYNTHROID (sodium levothyroxine) TABLET is equivalent to approximately one grain thyroid, U.S.P. Administer SYNTHROID tablets as a single daily dose, preferably after breakfast. In hypothyroidism without myxedema, the usual initial adult dose is 0.1 mg. daily, and may be increased by 0.1 mg. every 30 days until proper metabolic balance is attained. Clinical evaluation should be made monthly and PBI measurements about every 90 days. Final maintenance dosage will usually range from 0.2-0.4 mg. daily. In adult myxedema, starting dose should be 0.025 mg. daily. The dose may be increased to 0.05 mg. after two weeks and to 0.1 mg. at the end of a second two weeks. The daily dose may be further increased at two-month intervals by 0.1 mg. until the optimum maintenance dose is reached (0.1-1.0 mg. daily).

Supplied: Tablets: 0.025 mg., 0.05 mg., 0.1 mg., 0.15 mg., 0.2 mg., 0.3 mg., 0.5 mg., scored and color-coded, in bottles of 100, 500, and 1000. Injection: 500 mcg. lyophilized active ingredient and 10 mg. of Mannitol, N.F., in 10 ml. single-dose vial, with 5 ml. vial of Sodium Chloride Injection, U.S.P., as a diluent. SYNTHROID (sodium levothyroxine) for Injection may be administered intravenously utilizing 200-400 mcg. of a solution containing 100 mcg. per ml. If significant improvement is not shown the following day, a repeat injection of 100-200 mcg. may be given.

Health Care Delivery

RICHARD E. YA DEAU, M.D.*

OUR MEDICAL COMMUNITY has been responsive to demands placed upon it to insure adequate training of physicians through appropriate licensure laws. More recently new pressures arose as a series of legal decisions extended the concept of accountability beyond the patient-doctor relationship: institutions have been held responsible for the quality of medical care delivered within their doors. The former concept of quality control depended upon input measures to assure that patient care was appropriate; the latter, upon malpractice to punish when care was inadequate.

Public law 92-603 has turned away from each of these avenues. It undertakes to create an ongoing program of quality assurance. It contains elements of quality assessment and quality control. It directs itself to the necessity of medical care delivered, its quality, and the facility in which it is rendered.

This paper represents the highlights of the Foundation For Health Care Evaluation's presentation to the physicians of the Metropolitan area last March.

Analysis of the Law

PSRO means Professional Standards Review Organization. Public law 92-603 requires that there be created a National Professional Standards Review Council. In each state where three or more PSRO's exist, there shall be a State Professional Standards Review Council. Furthermore, establishment of a Professional Standards Review Organization by the physician community must occur before 1976, or, should they decline to do so, other knowledgeable people may be so appointed.

Broad Concepts

There are basically three constructs available to physicians today which will enable them to live under public law 92-603. The first comes from New Mexico where the concept of a PSRO as a central authority has been established. That central authority projects itself into every member institution and does for those institutions those

things which we traditionally hold as being the privilege of the institution. In essence this will construct a central authority from which goes out all power and under which each institution must live.

The second concept is a smaller central authority: smaller because it sends its designee to function within each institution. This central authority selects and trains people who will function within an institution, available for consultation and dialogue, but basically retaining the right, the power and the authority to run pre-admission screening, utilization review and quality assurance (quality assessment and quality control) in the institution. This is very similar to the HASP program in Illinois where there is a designee in each institution for utilization review.

The third concept available to the medical community today does not have a major central authority performing all activities and does not have a smaller central authority with designees in every institution. It is the concept embodied in the programs of Minnesota's Foundation For Health Care Evaluation. This concept is one where the PSRO acts as a guarantor that appropriate activities which fulfill federal law 92-603 occur within each institution. The hospital medical staff of each institution would be organized to relate with the PSRO as it accomplishes the utilization and quality assurance programs. By reducing in each institution the physician committee commitment to a single set of functions fulfilling both the public law and those functions related directly to their own hospital board, a continued reduction in required physician time is anticipated. The PSRO then stands not as a central authority, but as a guarantor on behalf of the medical community, physicians, administrators, patients and governing boards.

These are the three options that we have available to us today. There is no way to predict what the physician response will be, but it is hoped that by looking at the measured steps with which this law was constructed, all will agree that the option of enabling every institution to do these

*President of the Foundation for Health Care Evaluation and Chief of Staff of Bethesda Hospital, St. Paul.

activities themselves is a superior route to allowing a central authority to make these decisions in another's behalf.

The basic tenet running through the Foundation proposal is the belief that the hospital medical staff committees can function to fulfill the requirements of public law 92-603. Within the state of Minnesota there have been many hospitals able to look at quality assessment and to perform a benchmark job.^{1,2} The tools to accomplish these functions are available today.

A corollary to the Foundation's faith in the hospital medical staff committees is the belief that there are established organized relationships in each hospital which can be structured to compile a reporting document usable by both the individual institution and the Foundation For Health Care Evaluation to fulfill the requirements of this law.

The Foundation proposal is a different format.

It acts as a guarantor, being a recipient of documents, not the purveyor of these types of activities. Hence this PSRO design would be able to cover a larger area and to provide less disturbance and dislocation of practice patterns within the individual institution. These concepts will be valuable regardless of the PSRO designation because there is a right within the law for an institution to escape PSRO authority if it can develop appropriate self-controls. In designing this program there is the assumption that every one of the hospitals represented, every one of the physicians within the community would prefer not to function under a central authority, but would prefer to function in a responsible manner within the framework of their governing board. With that assumption, taking these programs, it is reasonable to expect an institution would be able to rise out of whatever restraints might be designed by any subsequently constructed PSRO.

A Study of Public Law 92-603

The Law

Sec. 1152 (b) (1) (A):

"An Organization

"(ii) which is composed of licensed doctors of medicine or osteopathy engaged in the practice of medicine or surgery in such area."

"(iii) The membership of which includes a substantial proportion of all such physicians in such area."

Sec. 1155 (d):

"... Each PSRO ... shall ...

"(1) Encourage all physicians practicing ... in the area ... to participate as reviewers in the review activities ..."

"(2) Provide rotating physician membership of review committees ..."

"(3) Assure that membership on review committees have the broadest representation feasible ..."

The Interpretation

Organizational Requirements:

As the law is constructed, it initially requires that the PSRO be a physician organization, the word "physician" including all medical doctors and doctors of osteopathy.

The physicians who make up the PSRO must be representative of the area. This means that there is no way that a group at the Foundation For Health Care Evaluation or any other group can be appointed without physician advice and consent. Ten percent of the physician community can require an open election. In an open election 51 percent of those people voting (not of the total electorate) are necessary to bring a PSRO designation.

Not only must physicians agree to be served by the PSRO; they must agree to serve for the PSRO.

Rotating participation on the reviewing panels and committees insures that all physicians ultimately have an opportunity to affect the elements ultimately designated as good medical practice.

HEALTH CARE DELIVERY

The Law

Sec. 1155 (a) (5):

"Physicians . . . may be only those having active hospital staff privileges in at least one of the participating hospitals in the area."

The Interpretation

Reviewer Qualifications:

A specified reviewer qualification is the requirement that every physician so designated have active membership on a hospital medical staff within the area. Additionally we find that the Joint Commission on Accreditation of Hospitals is working very strongly to insure that physicians are not denied active hospital medical staff membership in lieu of a more specific deliniation of their privileges.

Review of Professional Activities

Sec. 1155 (a) (1):

" . . . It shall be the duty . . . of each PSRO to . . . determine whether—

"(A) Such services and items are or were medically necessary"

"(B) The quality of such services meets professionally recognized standards"

"(C) . . . Such services and items could . . . be effectively provided on an outpatient basis or more economically in an inpatient health care facility of a different type"

with respect to "the professional activities of—

"physicians

"other health care practitioners

*"institutional and noninstitutional
providers of health care services"*

Suffice it to say that these activities as to necessity, quality and point of service (i.e. facility) must be done for all physicians in the area and for the institutions, namely hospitals. In essence, the necessity, quality and location of health care delivery will be spelled out under the requirements of federal law in a physician specific and institution specific manner.

Sec. 1155 (e) (1):

"Each PSRO shall utilize the services of and accept the findings of a hospital or other operating health care facility or organization . . ."

Hospital review committees have an option to affect these activities. What a PSRO may do is request of the audit committees in the hospitals that they accomplish these activities with respect to the quality of surgery or medicine delivered and subsequently take the findings as a basis for their determinations. This is extremely critical as the Foundation is assuming that every hospital staff committee can function at an appropriate level so as to provide a PSRO with these findings and insure that the central authority will not have to intercede.

" . . . But only when and only to the extent and only for such time that such committees in such hospital or other operating health care facility or organization have demonstrated to the satisfaction of . . . (the PSRO) . . . their capacity effectively and in timely fashion to review activities . . ."

However, the hospital staff committees must provide programs which are equal to or better than the programs that would be mounted by the central authority. Every hospital can make its committees function in a manner allowing escape from an outside, nonresponsive controlling organization, but they cannot escape from documentation and reporting.

The Law

Sec 1156 (a):

"Each PSRO shall apply professionally developed norms of care, diagnosis, and treatment based upon typical patterns of practice in its regions . . . as principal points of evaluation and review."

Sec. 1156 (a):

"Where the actual norms of care, diagnosis, and treatment in a PSRO area are significantly different from professionally developed regional norms of care . . . the PSRO shall be so informed."

"And in the event that appropriate consultation and discussion indicate reasonable basis for usage of other norms in the areas concerned, the PSRO may apply such norms."

The Interpretation

All of this activity deals with "health care norms," or standards. By law the medical community must be responsive to developing the standards against which practice will be measured. If the local health care community cannot develop the standards itself, then the National Professional Standards Review Council is prepared to afford the region those standards under which it must live.

Thus, there is an option to create local standards against which local care will be measured and judged, providing they are open, displayed and available for people to understand. If that opportunity is declined, there exists legal responsibility to live up to the standards that will be promulgated from Washington—promulgated without interchange and consultation of local physicians.

These local health care norms must deal with the common diseases that are every day occurrences; they must be disease specific and specific for the facility in which care is delivered.

There is a clause within the law concerning local health care norms: If the physicians, those who are providing medical care, can define on a local basis good medical practice and support this definition with adequate evidence, local norms can override the national and can be applied to local practice in lieu of national norms.

Each local region thus must spell those norms out and present them to the federal authority. There is, however, no reason to expect that the federal authority will be other than responsive to these norms as they are required by law to accept local variations where adequately documented justification exists.

Locally derived health care norms would, by the concept here-in conceived, be documented and reported by the institutions. Such norms must cover preadmission screening, utilization review, and quality assessment. In a local area, if this concept is endorsed, this means physicians are prepared to develop their own standards, define local good medical practice and do their own adjudication, using the member institutions.

HEALTH CARE DELIVERY

The Law

Sec. 1155 (a) (2)

"Each PSRO shall have the authority to determine, in advance . . . whether such service . . . would meet the criteria specified in clauses (A) and (C) (i.e. medical necessity and appropriateness of facility) in the case of

"(A) any elective admission to a hospital, or other health care facility

"(B) any other health care service which will consist of extended or costly courses of treatment."

Sec. 1156 (d) (1):

"Each PSRO shall . . .

"(A) specify the appropriate points in time after admission . . . at which the physician attending the patient shall execute a certification stating that further inpatient care will be medically necessary,"

(B) including "such information as may be necessary to enable such organization properly to evaluate the medical necessity of the further institutional health care"

The Interpretation

If the physicians are willing to perform these determinations, then by Public Law 92-603 these physician determinations must be accepted. That is, the local hospital organizations, the local hospital medical staffs can be responsible to this law, can make their decisions mandatory and binding and can affect 40% of the health care dollars flowing into area institutions.

Preadmission Screening

Preadmission screening essentially says that on every elective admission the necessity, quality and facility must be determined in advance, based on a dollar specific approach. Preadmission screening, if inappropriately designed could be so strident as to say "Doctor, you're admitting somebody with abdominal pain. Since this isn't an emergency, I'd like to see the documentation of all your workup for abdominal pain *before* you bring this patient into this institution."

This approach is comparable to the CHAP program design. If the medical community does not have a better answer, physicians will find the practice of medicine under preadmission screening fairly onerous as this concept would require the physician to provide full documentation from his office before any Social Security patient could be admitted to a hospital. Further, this concept would go so far as to require that this documentation be provided to a screener in the hospital who would then construct the initial day allowance, or the initial number of days that a patient could stay.

Utilization Review

Public law 92-603 also requires utilization review. It says specifically that the review requires the attending physician to create a certificate in which he documents the specific reasons he deems further hospitalization necessary. Thus, there must be some type of an update note that will fulfill this law, based on the record that is being constructed within the hospital.

The Law

"... not later than the 50th percentile of lengths of stay for patients in similar age groups, with similar diagnoses requiring various types of health care services or procedures."

Sec. 1161:

"Whenever any . . . determination—

"(a) denies any request . . . for approval of a health care service . . ."

(b) concludes . . . "that any such practitioner or provider has violated any obligation imposed . . ."

then . . . "immediately after taking such action or making such determination, give notice to such practitioner or provider of such determination and the basis therefore, and shall provide him with appropriate opportunity for discussion and review . . ."

Sec. 1158 (a) (2) & (b):

When . . . "such organization or other agency has . . . disapproved of the services or items . . . such organization shall" notify—

"... the practitioner or provider who provided or proposed to provide such services or items

"... the individual who would receive or was proposed to receive such services or items

"... The agency or organization having responsibility for acting upon claims for payment."

The Interpretation

While the Foundation would have preferred Congress to accept the 75th percentile review, they declined to do so and constructed their review at the 50 percentile. "Percentile" means the percentile of expected stay with like patients. For example, a patient has his gallbladder removed at hospital X. On day ten, 50% of those people would have gone home, thus on day ten the utilization review committee in hospital X looks at the medical record of this patient, searching for documentation that he could not have been served more rapidly and, indeed, that he continues to require institutional service.

This type of utilization review is not meant to escape the usual legal constraints and has included the right to notice, hearing and appeal. Whenever a request for a continued stay is denied, the doctor must be notified and given an opportunity to interface with the utilization review committee and explain why this patient still requires hospitalization.

Notification of disapproval is quickly provided under the law, not only to the hospital and the physician, but is also provided to the patient and to the fiscal intermediary, thus not allowing for the delaying tactics of interminable discussion.

*The Law**Sec. 1155 (a) (4):*

"Each PSRO shall . . . (maintain and regularly review) . . . profiles of care and services received and provided—

" . . . with respect to patients

" . . . with respect to each health care practitioner

" . . . with respect to each care provider

" . . . to determine whether the care and services ordered or rendered are consistent with the criteria specified."

Sec. 1160 (a) (1):

"It shall be the obligation of any health care practitioner and . . . any hospital or other health care facility . . .

"To assure that services or items ordered or provided . . . to beneficiaries . . . under this act—

"(A) will be provided only when, and to the extent, medically necessary

"(B) will be of a quality which meets professionally recognized standards of health care

"(C) will be supported by evi-

**The Interpretation
Quality Assessment**

These elements of the law were already strident enough. Section 1155 moves into a very interesting area, legislating the maintenance and review of profiles with respect to patients served, with respect to the physician performing the service and with respect to the hospital.

Further, these profiles must be brought together into a cluster so that it is apparent if any of the physicians, hospitals, or patients are providing or being provided inappropriate care.

Are these profiles not much better at home within the individual hospital medical staffs than they are in the hands of a central authority?

The Joint Commission on Accreditation of Hospitals has already decided that in the very near future each institution will have such profiles for the credentialing and recredentialing processes. At the accreditation survey an institution might say, "This physician has the right to handle a diabetic in ketone-acidosis." The response of the JCAH will be: "All right, Mr. Hospital Medical Staff, on what grounds do you have to provide that physician with the privilege of treating diabetics in ketone-acidosis? Let us see his performance pattern. Let us see documentation that shows that he has had training. Or, if you can't show us that he has training, at least show us that he has been adjudged competent by your hospital medical staff and, in addition, show us his experience."

This is coming from the Joint Commission as an accreditation requirement.

Practitioner and Provider Obligations

Many who read this law feel that the law deals with PSRO's alone. It also deals with physicians. Everything to this point deals with the requirements necessary to monitor the necessity of medical care, quality of medical care and the facility in which it's delivered. But, there is a whole other segment—section 1160 which defines the responsibilities placed upon the health care practitioners regardless of PSRO activities.

This is the first time that these physician obligations have ever been spelled out in writing. Specifically, physicians will be held responsible for the services delivered: for the necessity, for the quality and for the evidence thereof.

*The Law
dence of such medical neces-
sity and quality."*

The Interpretation

Section C of the law requires every physician to create a document which will support necessity and quality. In a very specific fashion, the law is saying that a physician who does not create an adequate medical record documenting his care, by definition is not providing quality medical care.

The law spells out the physician requirement to create documentary evidence which supports his patient care programs. If the care is not so supported in the medical record, then by definition, it was not provided and care will not be remunerated . . . the dollars will not be given.

* * * *

Proposals of the Foundation for Health Care Evaluation

Preadmission Screening

Of all the programs, preadmission screening will be the most difficult for the medical community to live with. It could function in any one of three ways: through a central authority, through a hospital-based designee of a central authority, and through an institutional program such as the one the Foundation proposes.

The first method has a central authority telephone exchange and document reception point. The physician wishing to electively hospitalize a patient will call that telephone authority where non-physician personnel will reference a book of protocols specifying the tests required prior to hospitalization. For example, looking up abdominal pain, the protocol might read, "The patient should have had testing such as IVP, colon, upper GI, gall bladder and procto prior to hospitalization." The physician must supply the central authority with the documentation of these tests before he can receive an initial day allowance for hospitalization.

In the second approach, every institution has within its structure a representative of the central authority who performs these tasks. This method is a little better in that the designee has the opportunity to interface with the hospital, physicians and administration. However, that administration still has no authority over that designee. That designee is bought, owned and loyal to the PSRO.

The Foundation is proposing that preadmission start through an effort of our member institutions

working through the Foundation to develop standards. Remembering that standards are *required*, these proposals emphasize local development rather than federal, implementing them in the hospitals where health care is actually delivered with the Foundation acting as a monitor.

The Foundation will guarantee that the activities in each institution are appropriate and will guarantee that the hospital committees are not constructing a whitewash to favor a few admitting physicians. On the other hand, the Foundation believes that the institutional physician committees should be responsive to the needs of the patients and their physicians. Thus, the institutional evaluation of the elements of good medical practice will indeed reflect the health care rendered in the institution.

These standards must include at least two sets. First, the standards will include a list of those diagnoses and therapies ordinarily handled outside the hospital. Given such a list of conditions when a physician admits a patient included on the listing he can be asked to document those unique characteristics which necessitate admission of the patient.

The second set to which the standards must address themselves are those diagnoses and therapies which are usually found within the institution. These standards should delineate the normal profile of activities, tests, etc., to be accomplished prior to hospitalization plus reasonable examples.

Once constructed by the area hospital staff committees and the Foundation for Health Care Evaluation the preadmission screening profiles will be

published as required by law. An admitting physician will then have two options. In the first option he simply admits the patient and states in the medical record that he is in compliance with the standards. In the second option the physician is allowed to override the constructed preadmission profile standards. However, he must state in the admitting note that he is overriding the preadmission profile and also specify his reasons for doing so.

Note that as yet neither a central authority nor a committee has been placed between the physician and his freedom to admit a patient to the hospital when he deems it necessary. The Foundation proposes that a committee review only those physicians who have more than 10% over-ride or more than 10% statements that they complied to the standards when their records do not substantiate this claim. At this point, the committee would review the physician's reasons for overriding, deciding either of two things: (1) that it represents good medical practice or (2) that it presents a deficiency.

In the first case, the committee agrees that the physician was working in the best interest of his patient and that the variation from the standards was in keeping with that patient's total needs. In the second case where the committee decides that a deficiency exists, that physician and that physician alone would be required to complete a preadmission document (certificate), and then only for a limited period of time. In other words, if a physician fails to comply with the preadmission standards and also fails to document the rationale for that override, his own committee then decides that there is a deficiency and requires him to create those numerous preadmission certification documents.

Utilization Review

The utilization review program has been designed to be patient specific, taking into account at the 50th percentile the patient's age, primary diagnosis, any operations that are performed; any complications that occur while the patient is in the institution and any other concurrent disease conditions.

This program requires the attending physician to complete a *short* update note, specifying the diagnosis, indicating the length of time he intends to keep the patient hospitalized and the reasons for this additional hospital time is necessary, and specifying his dismissal plans.

A representative of the hospital committee then

reviews the documents, verifying the medical necessity as documented in the record. Thus, if an inappropriate record has been created, the case will be disallowed not on the basis of the care provided, not on the basis of how sick the patient is, but on the basis of inadequate documentation. It should be pointed out that this is already the reason many patients have found themselves disallowed by Medicare, not because the care was not needed, but because the physician failed to successfully document that need.

The disallowal procedure takes into account very specifically the concepts of notice, hearing and appeal. Namely, as soon as the utilization review physician recognizes a patient who, by virtue of the record, should not be hospitalized, he contacts the attending physician. The attending physician then has the opportunity to change his record to reflect the patient's actual need or, if the record does reflect the patient's actual need, to initiate discharge procedures.

If the utilization review physician contends that the patient should not be hospitalized and the attending contends that he should, a designee of the chief of service or utilization review committee chairman will review the case. This guarantees that a patient is not sent home, is not disallowed medical services that he should be afforded.

All parties are to be put on notice and given a hearing *prior to* the dissolution of the fiscal obligation, rather than simultaneous to or subsequent to such dissolution. Appeal should be an appeal in fact, rather than an appeal in theory.

Quality Assessment

The final program deals with quality assessment. The bases for quality assessment are quality standards, or health care norms, against which all practice is compared. Quality standards can be defined as the appropriate elements of care, or "study criteria," plus all the exceptions to those study criteria which also reflect good medical practice. For example, if the study criteria deal with the appropriateness of Cesarean sections being done by the classical route versus the low cervical route, those exceptions in which the classical Cesarean is synonymous with good medical practice should be delineated.

Having institutionally determined study criteria against which medical care can be measured, the institutions would then be asked to create data displays. These displays would compare actual practice against the study criteria, thus allowing

the institutions to determine whether their practice is equal to or is dissimilar from the standards. These data displays can be created by a medical data analyst, a non-physician who does not make judgments as to what is good medical practice but merely compares side-by-side what physicians said they could deliver against what they actually are delivering.

Physicians then review any variations, deciding when a variation represents good medical practice and when it represents a deficient practice pattern.

Deficient practices then should be submitted to a deficiency analysis to determine the deficient agent (the whole hospital? a service? a cluster of physicians? one physician? a system?) and to determine whether one is dealing with a problem of knowledge or of performance.

The answer to these questions determine the corrective action to be mounted . . . whether a system is changed, an education program is conducted, a physician is counseled, new equipment is purchased, etc. . . .

The Foundation recognizes that there will have to be study criteria and that these will ultimately become standards. Exceptions must be spelled out and data displays constructed by the hospital medical record room. Each institution must handle in its committees all variations from normal, deciding what is good medical practice. Each must

be prepared to discover what is a deficiency and whether it's one of knowledge or performance. Each must ask the big question, "Who is the one who is deficient?" and from this design appropriate corrective action.

THE GOAL IS GOOD MEDICAL CARE!!

Conclusion

The Joint Commission on Accreditation of Hospitals has reviewed these programs and found them to completely fulfill their accreditation requirements. They are prepared to require this type of mature committee activity in every member institution that is accredited. To quote Charles Jacobson, J.D., Associate Director of the JCAH from his comments at the March 15 Foundation Staff meeting:

"The Joint Commission's new standards really predate anything you have heard concerning PSRO's. While essentially the Joint Commission's standards say nearly the same thing, we are interested in all patients and would say that all of those quality assurance mechanisms should be applied to every patient treated at the institution."

The real decision now is whether these types of activities are going to occur in a central authority where there is no recourse or whether it will be done at home in the hospital structure. As each of you make this decision, consider these words from the writings of Plato:

THE PUNISHMENT OF WISE MEN WHO REFUSE TO TAKE PART IN THE AFFAIRS OF GOVERNMENT IS TO LIVE UNDER THE GOVERNMENT OF UNWISE MEN.

University of Minnesota Medical School—Minneapolis

Special Issue

Everybody experiences psychic tension.

Most people can handle this tension.

Some people develop excessive psychic tension and need your counseling

and a few may need counseling
and the psychotropic action of Valium® (diazepam).

Before deciding to make Valium (diazepam) part of your treatment plan, check on whether or not the patient is presently taking drugs and if so, what his response has been. Along with the medical and family history, this information can help you determine initial dosage, the possibility of side effects and the ultimate prospects of success or failure.

While Valium can be a most helpful adjunct to your counseling, it should be prescribed only as long as excessive psychic tension persists and should be discontinued when you decide it has accomplished its therapeutic task. In general, when dosage guidelines are followed, Valium is well tolerated (see Dosage). For convenience it is available in 2-mg, 5-mg and 10-mg tablets.

Drowsiness, fatigue and ataxia have been the most commonly reported side effects.

Until response is determined, patients receiving Valium should be cautioned against engaging in hazardous occupations requiring complete mental alertness, such as driving or operating machinery.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anti-convulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect.

Adults: Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. **Geriatric or debilitated patients:** 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) **Children:** 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 100 and 500. All strengths also available in Tel-E-Dose® packages of 1000.

Acute arthritic inflammation...heat that freezes

In acute rheumatoid arthritis consider Tandearil. The anti-inflammatory action of Tandearil quickly helps reduce heat, pain, swelling, and stiffness. Results are usually seen in 3 or 4 days. Try it for a week when the symptoms defy aspirin control.

Remember that Tandearil is not a simple analgesic. It should not be used in patients responding to routine therapy. Before using, please read the prescribing information. It's summarized below.

Tandearil® helps take the heat off phenylbutazone NF Geigy

Tablets of 100 mg.

Important Note: This drug is not a simple analgesic. Do not administer casually. Carefully evaluate patients before starting treatment and keep them under close supervision. Obtain a detailed history, and complete physical and laboratory examination (complete hemogram, urinalysis, etc.) before prescribing and at frequent intervals thereafter. Carefully select patients, avoiding those responsive to routine measures, contraindicated patients or those who cannot be observed frequently. Warn patients not to exceed recommended dosage. Short-term relief of severe symptoms with the smallest possible dosage is the goal of therapy. Dosage should be taken with meals or a full glass of milk. Patients should discontinue the drug and report immediately any sign of: fever, sore throat, oral lesions (symptoms of blood dyscrasia); dyspepsia, epigastric pain, symptoms of anemia, black or tarry stools or other evidence of intestinal ulceration or hemorrhage, skin reactions, significant weight gain or edema. A one-week trial period is adequate. Discontinue in the absence of a favorable response. Restrict treatment periods to one week in patients over sixty.

Indications: Acute gouty arthritis, rheumatoid arthritis, rheumatoid spondylitis.

Contraindications: Children 14 years or less; senile patients; history or symptoms of G.I. inflammation or ulceration including severe, recurrent or persistent dyspepsia; history or presence of drug allergy; blood dyscrasias; renal, hepatic or cardiac dysfunction; hypertension; thyroid disease; systemic edema; stomatitis and salivary gland enlargement due to the drug; polymyalgia rheumatica and temporal arteritis; patients receiving other potent chemotherapeutic agents, or long-term anticoagulant therapy.

Warnings: Age, weight, dosage, duration of therapy, existence of concomitant diseases, and concurrent potent chemotherapy affect incidence of toxic reactions. Carefully instruct and observe the individual patient, especially the aging (forty years and over) who have increased susceptibility to the toxicity of the drug. Use lowest effective dosage. Weigh initially unpredictable benefits against po-

tential risk of severe, even fatal, reactions. The disease condition itself is unaltered by the drug. Use with caution in first trimester of pregnancy and in nursing mothers. Drug may appear in cord blood and breast milk. Serious, even fatal, blood dyscrasias, including aplastic anemia, may occur suddenly despite regular hemograms, and may become manifest days or weeks after cessation of drug. Any significant change in total white count, relative decrease in granulocytes, appearance of immature forms, or fall in hematocrit should signal immediate cessation of therapy and complete hematologic investigation. Unexplained bleeding involving CNS, adrenals, and G.I. tract has occurred. The drug may potentiate action of insulin, sulfonylurea, and sulfonamide-type agents. Carefully observe patients taking these agents. Nontoxic and toxic goiters and myxedema have been reported (the drug reduces iodine uptake by the thyroid). Blurred vision can be a significant toxic symptom worthy of a complete ophthalmological examination. Swelling of ankles or face in patients under sixty may be prevented by reducing dosage. If edema occurs in patients over sixty, discontinue drug.

Precautions: The following should be accomplished at regular intervals: Careful detailed history for disease being treated and detection of earliest signs of adverse reactions; complete physical examination including check of patient's weight; complete weekly (especially for the aging) or an every two week blood check; pertinent laboratory studies. Caution patients about participating in activity requiring alertness and coordination, as driving a car, etc. Cases of leukemia have been reported in patients with a history of short- and long-term therapy. The majority of these patients were over forty. Remember that arthritic-type pains can be the presenting symptom of leukemia.

Adverse Reactions: This is a potent drug; its misuse can lead to serious results. Review detailed information before beginning therapy. Ulcerative esophagitis, acute and reactivated gastric and duodenal ulcer with perforation and hemorrhage, ulceration and perforation of large bowel, occult G.I. bleeding with anemia,

gastritis, epigastric pain, hematemesis, dyspepsia, nausea, vomiting and diarrhea, abdominal distention, agranulocytosis, aplastic anemia, hemolytic anemia, anemia due to blood loss including occult G.I. bleeding, thrombocytopenia, pancytopenia, leukemia, leukopenia, bone marrow depression, sodium and chloride retention, water retention and edema, plasma dilution, respiratory alkalosis, metabolic acidosis, fatal and nonfatal hepatitis (cholestasis may or may not be prominent), petechiae, purpura without thrombocytopenia, toxic pruritus, erythema nodosum, erythema multiforme, Stevens-Johnson syndrome, Lyell's syndrome (toxic necrotizing epidermolysis), exfoliative dermatitis, serum sickness, hypersensitivity angitis (polyarteritis), anaphylactic shock, urticaria, arthralgia, fever, rashes (all allergic reactions require prompt and permanent withdrawal of the drug), proteinuria, hematuria, oliguria, anuria, renal failure with azotemia, glomerulonephritis, acute tubular necrosis, nephrotic syndrome, bilateral renal cortical necrosis, renal stones, ureteral obstruction with uric acid crystals due to uricosuric action of drug, impaired renal function, cardiac decompensation, hypertension, pericarditis, diffuse interstitial myocarditis with muscle necrosis, perivascular granulomata, aggravation of temporal arteritis in patients with polymyalgia rheumatica, optic neuritis, blurred vision, retinal hemorrhage, toxic amblyopia, retinal detachment, hearing loss, hyperglycemia, thyroid hyperplasia, toxic goiter, association of hyperthyroidism and hypothyroidism (causal relationship not established), agitation, confusional states, lethargy; CNS reactions associated with overdosage, including convulsions, euphoria, psychosis, depression, headaches, hallucinations, giddiness, vertigo, coma, hyperventilation, insomnia; ulcerative stomatitis, salivary gland enlargement.

"Prescription drugs – who should determine the maker?"

Dispenser of Medicine

Clifton J. Latiolais
President
American
Pharmaceutical
Association

Maker of Medicine

C. Joseph Stetler
President
Pharmaceutical
Manufacturers
Association

"Too many doctors are dependent on the economic consequences of their decisions." So stated an issue of *Medical News Report* (December 4, 1972), an independent weekly newsletter published by AMA Chief Executive F. J. Long, M.D.

Doctor, are you indifferent...

In discussing an anticipated increase in Blue Shield rates, *Blue Shield's* newsletter had this to say:

"In general, it can be said that doctors have given the impression that they are not particularly concerned with the increase in cost of health care to patients..."

"True, an MD's training is primarily scientific, but in the real world of practice, all of his scientific decisions have a price tag, or an economic impact. The economics of health care beckon the practitioner's attention. Concern for economics of medicine is a natural part of the physician's role."

When the pharmacist recommends that a drug product other than the one ordered be dispensed, the prescriber invariably permits the change when he feels the best interests of the patient will be served.

Shortcomings of Pro-Substitution Argument

The fact remains that it is necessary for the prescriber to know the change is being contemplated and to be in a position to comment or demur. Without that opportunity, a unilateral decision of the pharmacist made in the absence of clinical knowledge of the patient, could expose the patient to needless risks, and in addition, jeopardize the relationship between the professions of Pharmacy and Medicine. In my view, there is no offset in the pro-substitution argument that offsets these risks.

The Issue of Drug Knowledge

Substitution advocates claim that the primary justification for changing the rules is the desire to better utilize pharmacists' knowledge about drugs. Yet the pharmacist's task to keep current on the ever-changing field of drug therapy, to some extent, puts him at a disadvantage. Most often, a practicing physician will rely on expert knowledge of no more than

an obligation of medical
ce.
Medical societies ought to con-
tinuing campaigns to point
substantial savings that could
alized thru deductible insurance
protection for catastrophic ill-
At the very least, they should, in
patients' interest, question the
many insurance organization
is health care costs by forc-
holders to buy insurance

al care."

of drugs

Insurance rates and hospital
are only two factors in health

care costs. The cost of drugs—both
prescription and nonprescription—is
another.

And when it comes to drug
costs, the nation's pharmacists are
concerned. Through their national
professional society, the American
Pharmaceutical Association, pharma-
cists are advising the public to use
nonprescription medication cau-
tiously and conservatively, and to seek
the advice of their pharmacist before
selecting or purchasing such drugs.

Outdated Laws

The pharmacist also is aware
that when it comes to prescription
drugs, often he has an even greater
opportunity to reduce the cost to the
patient—with no sacrifice in the qual-
ity of the medication dispensed. But
in many states, outdated and anti-
quated laws prevent the pharmacist
from engaging in drug product selec-
tion. "Drug product selection" simply
means that the pharmacist functions
in the patient's interest by con-
sciously choosing, from the multiple
brands available, a low-cost quality
brand of the specific drug to be dis-
pensed in response to the physician's
prescription order.

Much *misinformation* has been
purposely spread by those who stand
to gain financially by maintaining

high drug costs to the public. An end-
less stream of propaganda has ema-
nated from the drug industry in an
effort to persuade the medical profes-
sion that these so-called anti-substitu-
tion laws should be retained. And as
long as these laws are retained, the
drug industry will continue its current
marketing practices which contribute
unnecessarily to high drug costs to
patients. These practices also are in-
viting government agencies to expand
their restrictive controls on physi-
cians and pharmacists.

APhA Efforts

As pharmacists, we are con-
cerned about health care costs. We
hope that every physician shares our
concern on this vital issue, and will
give his personal support to the con-
structive efforts APhA has undertaken
in the interest of all patients.

*(For a complete discussion of
drug product selection, you are invited
to request a free copy of the "White
Paper on the Pharmacist's Role in
Product Selection" from: American
Pharmaceutical Association,
2215 Constitution Avenue, N.W.,
Washington, D.C. 20037.)*

gs that he selects to treat the
of conditions encountered in
ice. Moreover, the physi-
choice of a specific brand is
his knowledge of the pa-
medical history and current
tin, and his experiences with
icular manufacturer's

ne substitution proponents
ued that the dispensing of a
ion is a simple two-party
on between the pharmacist
patient, and that a substitut-
macinist may avoid even a
breach of contract by simply
the patient that he is making
stitution. I would judge that
ts would be sympathetic
c pharmacist who substituted
physician approval and who
ok a legal defense that seeks
the patient responsible for
macinist's actions.

Prescription Prices?

stitution advocates are
ng to the consumer, and par-
the consumer activist, that
prescription prices could
galization of substitution.
seen absolutely no evidence
this claim. To the contrary,
ice in Alberta, Canada, where
tion is authorized, suggests

the opposite.

Many pharmacists understand-
ably are concerned about the cost of
maintaining multiple stocks of similar
products. While there is no doubt that
inventory costs rise when additional
brands are stocked, it would be inter-
esting to know how much they rise,
and how many pharmacists actually
stock *all* brands—of, say, ampicillin
or tetracycline—or how long they
keep "slow moving" products on their
shelves before they are returned for
credit. To ask that the industry elimi-
nate multiple sources is to ask com-
petitors to stop competing.

Drug Substitution—A License for the Unethical

Anti-substitution repeal would
favor "corner cutting" pharmacists
and manufacturers. For them, free
substitution would be not a right, but
a license. As an aftermath, it is quite
likely that the confidence of both phy-
sicians and patients in the profession
of Pharmacy would be eroded, as
revelations about the unconscionable
behavior of an undisciplined few were
magnified in the press or in profes-
sional circles.

Summary

In short, what the American
Pharmaceutical Association advo-

cates as a broad-spectrum panacea
looks to us to be not only a minority
view (advocacy of substitution is by
no means a uniform policy in Phar-
macy), but also an extraordinarily
costly and ineffective remedy, whose
side effects are odious. We believe
(1) that an impressive majority of
pharmacists prefer to work with
Medicine and with industry, for the
consumer, and for the general good,
(2) that they seek the privilege to sub-
stitute when the patient might gain
and when the patient's doctor agrees,
and (3) that they seek to work for the
resolution of genuine grievances
openly and professionally.

President's Letter

A LARGE PAIR of shoes is hard to fill, especially with small feet and more especially if the shoes are those of George Martin. He trod a mighty path as President of our venerable and honorable State Medical Association. To the task of leading us and representing us, he brought cool wisdom, admirable dignity and a wealth of experience serving the several medical groups he held in such high esteem.

To the people of his northwestern Minnesota community, he is a highly capable physician. The dedication and service he renders to them has been matched by the love he expresses for his profession in selfless leadership. For all of us his generosity to his family, his patients, and his colleagues should be a model.

Though his steps will be difficult to follow, let's hope that his successors will be able to muster the strength to at least try and especially, let's hope that this successor will be able to serve you in part with the skill and grace that he did.

Walter Lippmann said it well in his eulogy to Franklin Delano Roosevelt:

"The final test of a leader is that he leaves behind him in other men the conviction and will to carry on."

George did that—so let's have at it! May we keep in mind the debt we owe him for his service in our cause and express our gratitude by contributing as he does in the rank of our State Medical Association.

Sterilization of Women

A Review of New and Potentially Reversible Techniques

JOHN J. SCIARRA, M.D., Ph.D.*

THERE HAS BEEN a resurgence of interest in sterilization as a method of fertility control, especially as advances in bio-engineering technology hold out the possibility of reversible or temporary methods of sterilizing both men and women. This paper will concentrate on various methods of sterilizing fertile women, emphasizing new and experimental techniques, many of which may be reversibly reversed.

The structural diversity of the female reproductive system offers a number of different sites at which sterility can be produced. There are three types of such intervention: surgical, mechanical, and chemical. Some type or combination of types has been applied to almost every site.

This review will begin at the most distal site (the ovary) and move proximally down the reproductive tract to the uterus itself. One does not ordinarily think of the ovary as the site for sterilization. Oophorectomy and radiation castration have been used on occasion for sterilization purposes, but neither of these procedures is recommended, and they are now of purely historical interest. However, there is one technique of sterilization that depends on the mechanical obstruction of the ovarian surface. This is called ovariectomy.¹

Ovariectomy is the procedure by which the ovary is covered by a silastic pouch, which is then sutured to the supporting ligament. The ovary and its silastic envelope are buried within the broad ligament. Although follicles continue to develop and be released, the pouch prevents them from entering the fallopian tube. This technique has been applied to only a small series of patients. The original series of six women has now been followed

one to three years, and no complications have appeared. Biphasic basal body temperature charts indicate that these patients are ovulating normally; but no patient has had the procedure reversed.² The obvious disadvantage of this imaginative procedure is that laparotomy is required for placement of the silastic envelope and for its removal.

Fallopian Tubes

The next site for intervention is the fallopian tubes. By far the majority of sterilization procedures described in the literature involve the fallopian tubes. Most of the techniques currently under investigation are directed to the tubes or to the area of the uterotubal junction. Procedures will be discussed that relate to three anatomical areas:

1. the infundibulum and fimbriae;
2. the ampullary portion of the tube; and
3. the interstitial portion of the tube and the uterotubal junction.

An experimental technique effective in rabbits is fimbriectomy, the application of a silastic cap or hood to the fimbriated ends of the oviduct.³ In the laboratory, caps were affixed to the ipsilateral oviducts of rabbits. Several of the animals conceived through the contralateral oviduct, demonstrating that no extensive peritoneal reaction results from the procedure. After removal of the cap, animals conceived through the oviduct to which it had been applied. This technique has excellent potential for reversibility, although like ovariectomy, it necessitates laparotomy.

Many investigators have suggested the placement of intraluminal occlusive beads or devices as a method of reversible tubal sterilization. One such experimental technique that has been suggested for fimbrial obstruction is a notched teflon plug.⁴ This plug could be inserted by culdoscopy or laparoscopy. Studies on animals have demonstrated minimal tissue reaction with the plug in place. One-third of the animals became pregnant

*Professor and Head, Department of Obstetrics and Gynecology, University of Minnesota Medical School, Minneapolis, Minnesota. This manuscript prepared with the technical assistance of Martha Roth, A.B.

STERILIZATION OF WOMEN—SCIARRA

after removal of the oviductal plugs. This technique, like all others involving precise implantation, has the disadvantages of abdominal and/or vaginal surgery and the associated operative morbidity.

Many authors have reported techniques of temporary sterilization. Perhaps the most widely known was described years ago by Aldridge. In this operation the surgeon makes an incision in the broad ligament and inserts the fimbriated end of the tube, then closes the incision. The Aldridge

method is today only of historical interest, because although reversible, it was found to have significant failure rate. It also required major abdominal surgery.

The most effective surgical technique for sterilization that can be applied to the infundibulum of the fallopian tube is fimbriectomy, or amputation of the distal one-third of the tube. Partial or complete salpingectomy is an effective surgical procedure, which merits mention in any discussion of operative sterilization techniques.

STRUCTURE	METHOD	MECHANISM	REVERSIBILITY	DEVICE OR PROCEDURE
 Ovary	Oophorectomy	Surgical excision	No	Laparotomy
	Ovariectomy	Mechanical obstruction with silastic pouch	Yes?	Laparotomy
 Tubal infundibulum	Fimbriectomy	Surgical excision	No	Laparotomy or culpotomy
	Fimbriectomy*	Mechanical obstruction with silastic cap	Yes	Laparotomy
	Fimbrial plug*	Mechanical obstruction with notched teflon plug	Yes	Laparoscopy
	Aldridge procedure	Surgical burial	Yes	Laparotomy
 Fallopian tube	Salpingectomy	Surgical excision	No	Laparotomy or culpotomy
	"Ligation"—various procedures	Surgical interruption	No ⁺	Laparotomy or culpotomy
	Nonsurgical occlusion	Electrocautery	No?	Laparoscopy or culdoscopy
		Electrocautery with transection	No	Laparoscopy or culdoscopy
		Cryosurgical cautery	No ⁺	Laparoscopy or culdoscopy
		Application of clips	Possible	Culdoscopy or laparoscopy
 Utero-tubal junction	Nonsurgical destruction of ostia	Chemical sclerosis with e.g. quinacrine	Unknown	Transcervical blind delivery, positive pressure
				negative pressure
	Tissue-adhesive or other plugs	Mechanical obstruction	Yes?	Hysteroscopy
				Blind delivery [‡]
 Uterus	Hysterectomy	Surgical excision	No	Abdominal or vaginal
	Endometrial destruction	Chemical sclerosis with e.g. quinacrine*	Unknown	Transcervical delivery
		Cryosurgical ablation	Unknown	Uterine cryoprobe
	Timed release of drug	Chemical sclerosis of tubal ostia	Unknown	Intra-uterine device as carrier for drug delivery system [‡]

+ Procedure not designed for reversibility; possibility of reversal after 2nd surgical procedure

‡ Suggested possibility

Figure—Left

As was stated earlier, most sterilization techniques, present and past, are addressed either to the ampullary portion of the tube or to the uterotubal junction. Most of these methods are surgical. The Pomeroy technique of tubal sterilization is perhaps the commonest. The surgeon lifts a loop of tube; he then ties a plain catgut absorbable suture around the base of the loop, creating a knuckle; and then cuts across the knuckle, removing a segment of tube. As the suture material is absorbed, the normal tension of the broad liga-

ment pulls the cut ends of the tube apart.

There are many other surgical techniques of tubal sterilization and the technical details of most are well known. However, one of the newer procedures, described by Uchida,⁵ will be discussed.

In the Uchida procedure, the serosal surface of the tube is dissected away from its muscular portion, facilitated by the injection of saline-adrenalin solution to produce serosal ballooning. The saline-adrenalin injection also produces vascular spasm,

Figure—Right

permitting a bloodless dissection. The muscular tube is brought out through the cut serosa and transected; the proximal end of the cut tube is then stripped back and excised, and the distal stump is ligated and remains within the serosal balloon. The edges of the serosal incision are then gathered in a purse-string ligature, tied around the muscular limb of distal tube, and allowed to project into the abdominal cavity. In 1961, Uchida reported no failures in a series of nearly 5,000 patients on whom he performed this operation, but there has been no confirmed follow-up.

Wood² has developed a surgical procedure of considerable delicacy which he terms "atraumatic mid-ampullary sterilization," which may provide a good chance for surgical reversibility. It comprises the division of the wide, ampullary portion of the tube between the main blood vessels that supply it, followed by suture of the cut ends with no excision of tissue. The medial end is buried in a pocket cut in the mesosalpinx, which is then sutured closed over it. The extent of this operation makes it applicable to only a small number of patients. It is, however, potentially reversible with a second operation.

A large number of interval sterilization procedures performed today in many countries, including the USA, are carried out by either laparoscopy or culdoscopy, by means of electrocoagulation with or without accompanying tubal transection. This is an excellent procedure for sterilization; it is effective and has a relatively low rate of associated complications. The complications of this procedure which have been described are: (1) those related to general anesthesia, (2) those related to intra-abdominal hemorrhage, and (3) those related to electrical or thermal damage to intra-abdominal structures such as the small intestine. Laparoscopic sterilization may be done under regional or local anesthesia.

Simple laparoscopic electrocoagulation may be the commonest interval tubal sterilization procedure done in the USA today. Its effectiveness is directly related to the amount of tissue destroyed. If sufficient tissue is destroyed, recanalization is rare. Transection with destruction of the proximal tube also is a very effective method of sterilization.⁶

Other methods of endoscopic sterilization are cryocautery, with and without transection, and the application of metal hemoclips to the fallopian tubes. Because of its simplicity, tubal clipping

seems promising to many investigators. In theory it should be possible for these clips to hold the tubes closed without crushing them. In practice, however, sufficient tubal patency may remain for a pregnancy to occur.

Investigators are currently interested in refining this method. Gutierrez Najar⁷ suggests using two clips at each site rather than one; the tubes are placed 1 mm apart to prevent the hydrosalpinx that develops when they are more widely separated. Others have suggested changing the relative positions of the clips or the type of metal. A major concern associated with this procedure is the possibility of ectopic pregnancy, as reported recently by Neuwirth and associates.⁸ It is potentially an excellent reversible method.

Several procedures have been developed that are directed to the interstitial portion of the tube and the uterotubal junction. Excision of the cornual area has been used by some as a sterilization procedure. More recently, instillation of a sclerosing agent such as quinacrine, formalin, or paraformaldehyde, into the fallopian tubes at the uterotubal junction, is a method that various investigators have found to be successful. This technique lends itself to various delivery systems. Solutions may be instilled transcervically without anesthesia or by the use of either laparoscopic or hysteroscopic visualization.

The technique of hysteroscopy has become much more precise since the development of fiberoptics. In addition, the use of dextran as described by Edström and Fernström⁹ provides for greatly improved visibility. Quiñones and his colleagues have performed tubal electrocautery under hysteroscopic visualization and have found it to be a promising method.

The refinement of hysteroscopy has also led to some interesting experimental designs which use mechanical blocking agents applied to the uterotubal junction or, through the interstitial portion of the tube, to the lumen of the proximal ampulla. Some of these involve tissue adhesives which can be introduced in liquid form and which, as they rapidly solidify, constitute plugs that conform exactly to the shape of the passage they are blocking. One experimental proposal is for the development of a microporous interface which could be applied to the proximal end of the fallopian tube. Such a microporous plug would act as a differentially permeable membrane, permitting passage of fluid from the tubes into the

us but blocking entrance of sperm. These plugs could be removable.

Hysteroscopy, however, remains a sophisticated technique, even when performed under local anesthesia. Some current clinical research is directed at developing a transcervical method that would allow intervention at the uterotubal junction without requiring a high degree of training and skill from the operator. Zipper and his colleagues¹¹ have devised a blind transcervical delivery system for the injection of quinacrine to provide chemical intraluminal tubal sclerosis. The method is simple but requires several applications for maximum effectiveness.

An experimental transcervical technique of interest is that proposed by Thompson and co-workers.¹² This technique involves a curved, bent cannula which delivers a sclerosing agent into the cornual area of the uterus. This is done by blind manipulation. These investigators have also used a contrast-pressure technique, in which the uterine cavity is occluded by a small closed rubber balloon at the tip of a cannula, which is filled with CO₂ under pressure. The tip of the cannula is left open and through it the sclerosing agent is introduced at lower pressure into the lumen of the fallopian tube. These investigators and others are working to refine methods of blind delivery with such devices.

Finally, techniques directed to the uterus will be considered. Hysterectomy continues to be a widely used method of sterilization, especially when it is carried out vaginally. But other methods are also being addressed to the uterus. Zipper and Insunza have experimented with intra-uterine stillation in rats and rabbits of a variety of compounds, including quinacrine.¹³ Clinical experiments noted earlier have shown the destructive effect of quinacrine on tubal tissue. Sterilization by means of chemical ablation of the endometrium might be adaptable to use by paramedical personnel in large populations.

Cryosurgical ablation of the endometrium is now being studied as a means of sterilization. The extensive area to be frozen renders the procedure time-consuming, and the apparatus and its use are sophisticated. Injection of super-cooled liquids

might provide an alternative type of cryo-ablation. These procedures are currently under investigation by Droegemueller and his co-workers.¹⁴

A modality that appears most promising for use in large populations in the near future is the use of intra-uterine devices for controlled release of drugs, which could produce sclerosis of the tubal ostia and the interstitial portions of the tubes. There is an experimental device, developed by Tecna, Inc., (Emeryville, California), that can be inserted easily into the uterus. It contains channels which may be injected with fluid through the inserter. Such an IUD could have a drug compartment for the timed release of a sclerosing agent like quinacrine, as suggested by Butler.¹⁵ This could produce occlusion of the uterotubal junction and sclerosis of the upper uterine fundus. The advantage of such an engineering development would be preservation of the endometrium in the lower fundus, a feature which could make this sterilization technique more acceptable to many women.

Summary

Several portions of the female reproductive system have been the target of some method of sterilization, actual or experimental. The ovary can be removed, buried, or covered with a silastic obstruction; the infundibulum can be amputated, buried, plugged, or capped; the ampullary portions of the tubes can be removed, cut, tied, shortened, buried, burned, or frozen; the uterotubal junction can be scarred closed or plugged; and the uterus can be removed, frozen, scarred, or rendered mysteriously inhospitable.

A variety of assaults on the reproductive system have been described. No one technique is ideal for all women in all clinical or cultural situations, therefore, the research continues, for simpler techniques and for potentially reversible methods.

The fact that there is a resurgence of academic and research interest in sterilization of women is encouraging. Hopefully, it will continue, so that a safe, easy, effective, reversible, inexpensive procedure will be available to all women who desire sterilization.

Copper Seven Intrauterine Device

Clinical Experience

HARRY FOREMAN, M.D.*

THE USE OF INTRAUTERINE devices (IUD) to prevent conception has undergone successive waves of enthusiastic advocacy followed by periods of discouragement and disparagement when clinical experience has failed to bring out initial high expectations. Following a 30-year period of neglect and even condemnation, the use of the IUD underwent a remarkable revival during the 1960's when advances in technology permitted the fabrication of coiled plastic devices which could be straightened for insertion through tubes to be passed through the undilated cervix and then regain a space-filling configuration within the fundus. Because such devices could be produced simply and inexpensively, could be inserted by paramedical personnel trained in a relatively short time, and because they had the potential for remaining in place for months and years due to their inertness to tissue, there were high hopes that this method could be the near ideal contraceptive for use in bringing down fertility rates sharply in the lesser developed countries of the world. Unfortunately, extensive experience in Taiwan, Singapore, India, Thailand, etc., failed to bear out these expectations. Even though many different shapes and sizes were devised and used, the high frequency of side effects, uterine cramps, menorrhagia and expulsion, resulted in a disappointingly low retention and continuation rates, and the IUD again lost popularity.

Nonetheless, the IUD potentially remains a desirable contraceptive method, so active research to develop devices to alleviate or at least minimize the side effects has continued. Currently the most promising results appear to lie with devices which have incorporated into the plastic "active" chemicals which slowly release and act locally to contribute to the contraceptive efficacy of the devices. Among these are the progesterone loaded devices

of Horne, Scott and Underwood,⁴ and the so-called "copper T" and "copper 7" of Tatum and Zipper.¹¹ The latter, the subject of this report, consists of a 7-shaped device formulated from a copolymer of polypropylene and polyethylene which has thin copper wire (0.2 mm diameter and 32 mm in length) with a surface area of approximately 200 mm² wound around the stem. Barium sulphate is incorporated into the plastic to make it radio-opaque.

History of the Copper 7

The enhancement of contraceptive efficacy by the addition of copper to intrauterine devices was first demonstrated by Zipper et al. (1969) when these investigators discovered that copper prevented implantation of the fertilized ovum in the rabbit. These findings were later demonstrated in other animal species (Chang and Tatum²). Zipper et al.¹¹ in 1971 confirmed the potent contraceptive action of copper in humans in a study using a copper-wound T-shaped device. They also found that continuation rates were markedly better than reported for previously used devices by virtue of a reduction in uterine cramps, bleeding and expulsion rates.

Insights into the mechanism of action of copper were provided by Chang and Tatum² in studies on rats and rabbits where it was demonstrated that intrauterine copper renders the endometrium inhospitable to the blastocyst and therein prevents implantation. Blastocysts already implanted are not affected by insertion of copper into the uterus. Studies of serum and endometrial copper levels indicate no systemic absorption of copper (Zipper¹⁰). A cycle-related, localized activity of the copper is suggested by the demonstration of copper incorporated into the endometrium primarily during the progestative phase of the cycle (Medel et al.⁶). Loewit⁵ found that copper salts as well as

*Associate Professor, Department of Obstetrics and Gynecology, and Director, Center for Population Studies, University of Minnesota.

articulate metallic copper are spermatodepressive and at high concentrations, spermatocidal. Metallic copper, like most other intrauterine foreign bodies, evokes a marked mobilization of leukocytes throughout the endometrium and into the endometrial cavity (Cuadros and Hirsch³). It is reasonable to assume that the effects of metallic copper described above contribute either indirectly or collectively to its contraceptive action.

Normal fertility was found to be restored very quickly after removal of the copper from the uterus in rats and rabbits (Medel et al.⁶) and the removal of the device in humans for planning pregnancy was followed by normally expected pregnancy rates through the first trimester after extraction (Zipper et al.¹⁰).

Clinical Experience with the Cu7

Clinical experience with the Cu7 has been reported from Britain and the United States. The British, Newton, Elias and McEwan,⁷ report on 196.5 months of use by 342 women of "Gravidard," a Cu7 device manufactured and sold by the G. D. Searle Company. They found the device remarkably easy to insert. Insertion side effects decreased from 27% in the first month to 3% in the third month. The first expulsion rate per 100 users was 6.67, the accidental pregnancy rate, .08, and removal for medical reasons, 2.95, for the period they are reported (nine months). These findings compare very favorably to usage of the Lippes Loop under similar circumstances. They found the expulsion rate to be related to the care taken during insertion. The successful use of this IUD in the nulliparous woman (the first IUD that truly has exhibited this utility) represents a major addition to the armamentarium of contraception.

The American experience is reported by Bernstein, Israel, Seward and Mishell¹ using an experimental device supplied by Searle & Co. The study included 186 patients for a total of 1693 woman months. Fifty-nine percent of the women were nulligravida or nulliparous. They found insertion simple and non-traumatic. There were 1.1 pregnancies per 100 women for the first year of use. Expulsion rates were 4.1 per 100 users. Two of the six expulsions took place within six days of insertion suggesting inadequate intrauterine placement of the device. Removal rate for medical reasons (largely excessive bleeding and/or cramping) was 12.4 per 100 woman-years. In this study also,

the device was well tolerated by the nulliparous women.

The Minnesota Studies

The Minnesota studies are part of the Clinical Trials set up by Searle and Company in 1970 to provide information on the clinical experience with the Cu7 that could be submitted to the F.D.A.* The device that was inserted is the now standardized model: 35.9 mm long and 28 mm wide and wrapped with a length of copper which provides 200 mm² of surface area (Figure). The largest outside diameter of the folded device is 2 mm.

Patients were enrolled in two principal periods, during December-January of 1970-1971 and during January of 1972. Regular follow-up visits were required at one, two, three, six, twelve, and eighteen months post insertion (and every six months thereafter). At 18 months the devices were removed from some randomly selected patients, and a new one was inserted. In the remaining cases the devices are to be removed at 30 months post insertion. The removed devices are sent to Searle & Co. for their examination and study.

Figure

*We are indebted to G. D. Searle & Company for providing the devices and financial support for the study.

This study reports on the experience to date (January 30, 1973) with patients from five sources with somewhat differently structured populations. These included four clinics: (A) a University gynecological clinic staffed by residents, (B) a group serving private patients staffed by highly experienced gynecologists, (C) a Planned Parenthood clinic staffed by physicians of varied experience, and (D) a large county hospital gynecological clinic served by residents, and (E) the private office practice of a Board-Certified gynecologist.

Results (presented in Tables 1, 2, and 3)

Characteristics of the Populations

The study encompasses 2152 woman months of IUD use by 156 women from the five sources reporting. The ages and parities of the women served of the population sources are shown in Table 1. The women ranged in age from 18 through 40, although there were only three women in the 36-40 year old age group. By and large, the study population was a young group. Over 70% of patients were below 25 years, and 20% were below 20 years. Sixty-six percent of the group below 20 and 50% of the group below 25 were nulliparas. In view of the interest of an IUD suitable for use by the nullipara and the nature of the population reported here, the experience for the nulliparous women is broken out separately for analysis. The data were calculated by the life-table method of analysis (Potter⁸).

Pregnancies

A total of six unplanned pregnancies resulted: three occurring between 12-18 months of exposure, one at 20 months, and two in the 24th month. Since there were no pregnancies in the first year the failure rate for that time was zero. The clustering of three pregnancies during the second year yielded a cumulative of 2.04 per 100 nulliparous users and 4.99 for 100 users for both types of patients. Two were ectopic pregnancies, both in the 13-18 month period. One of them was to the only nullipara who became pregnant.

Expulsions

A total of 16 expulsions occurred, and these patients were dropped from the study. Most of them occurred during the first three months, five of them within five weeks of insertion. There was only one expulsion during the second year. The expulsions were equally distributed between the nulliparas and multiparas. The nulliparas who lost

their devices did this early, mostly within the first two months. There were no expulsions in the group after six months of use. The multiparas lost theirs throughout the entire period. The net result was that at the end of the first year the expulsion rate for the multiparas was 11.02 and for both groups, 10.09 per 100 users, with the same cumulative rate for the two years' experience.

Removals for Medical Reasons

It was necessary to have 23 devices removed for medical reasons, largely because of bleeding and pain. Other medical reasons included heavy vaginal discharge, a suspicious pap smear, and removal at surgery for a non-gynecological problem. The removals were more or less uniformly distributed over the whole period of the study and more or less equally divided between the nulliparas and the multiparas. The cumulative drop-out rate for medical reasons for 100 nulliparas use at the end of the first year was 10.14, similar to that for the whole group, 11.09. The cumulative drop-out rates for two years were also similar, namely, 16.0 per 100 users.

Removal for Personal Reasons

Most removals for personal reasons were for planning pregnancy, a total of eight. One device was removed because the woman planned a tubal ligation, another because her husband had had a vasectomy, and a third because the patient wished to have a Dalkon Shield inserted.

Lost to Follow-up

A small percentage of women (11 total) were lost to follow-up largely because of their leaving the area. The experience while they were under observation is included in this study.

End of Study

In keeping with the original protocol, the devices were removed for examination from the women selected randomly at the end of 18 months. These women were dropped from the study since no new devices were inserted.

Discussion

This is a first, and in a very real sense, preliminary report on an ongoing study. The experience is limited both in the number of women involved and in duration of time, but in view of the great interest in the copper 7—particularly for use by the young nullipara and the scarcity of data currently available—we are taking this opportunity to share our experience at this time. The principal value of our analyzing and reporting our data at this time is that on the basis of our findings

far, we are encouraged to continue to recommend the use of the Cu 7 in the nullipara.

We have limited our calculations and analysis to gross events particularly pertinent to the utility and efficacy of the device, namely, terminations due to accidental pregnancy, expulsions, and removals for medical reasons. In a later, final report we will include calculations yielding such information as net cumulative termination and continuation rates.

In considering the accidental pregnancies, it is worthy to note that there were no pregnancies during the first year. Such perfect experience is favorable, of course, compared with other reports for the first year of the copper 7 use of Bernstein, et al.¹ and Newton, et al.⁷ The pregnancy rates per 100 users for the two years can be compared to those reported for other devices for the same period, namely, 3.3 for the large Spiral and 5.1 for the Lippes Loop D (Teitze and Lewit⁹), versus 4.99 for all of our Cu 7 users and 2.04 for the nulliparous users.

The devices were in place in all of the women who had conceived. The device was removed from one of them at the time conception was recognized, but the pregnancy was not disturbed.

That two of the six pregnancies were ectopic is noteworthy, certainly a much higher rate than might be expected (Teitze calculates an expected rate in normal women of about one per 1,000) but this finding must be considered in the light of subsequent experience before its significance can be judged.

Three out of the four intrauterine pregnancies occurred late in the two year period, a fact which might be indicative of the loss of effectiveness of the device when much of the copper has been eluted from it due to tissue interaction.

Expulsion rates (10.09) were not nearly as favorable as those reported by Bernstein (4.01), but were comparable to those found by Newton (9.06) and the Lippes D (26.7). This can be considered a favorable experience, particularly in view of the high proportion of nulliparous women in our study. For these women the expulsion rates dropped essentially to zero after the first two months of use.

The rate of removal for medical reasons was favorable, 11.09 per 100 users, as compared to the Lippes Loop D (15.2) and all sizes of devices in the never pregnant women (17.3) (See Teitze and Lewit⁹).

Acknowledgment

The author wishes to thank the following people for their contributions to the Study:

Dr. Donald Freeman, Head, Department of Obstetrics and Gynecology, Hennepin County General Hospital, and Ms. Kaiser and Ms. Michalick, members of his staff, for providing us with the data collected on their patients in the study.

Dr. Jane Hodgson for her participation in the study using the device for her patients and providing data them.

3. Dr. Louis Mondy for making the facilities and patients of Planned Parenthood of Saint Paul available for inclusion in the study.

4. Dr. Fred Mecklenburg for making facilities and patients of the St. Louis Park Clinic available for the study.

5. Dr. John Sciarra, Head of the Department of Obstetrics and Gynecology at the University of Minnesota, for making the facilities of the University Ob-Gyn Clinic available for the study and for his valuable advice in preparation of the report.

6. Mr. David Paxson for his help in collection and collation of the data.

Squamous Cell Carcinoma of the Head and Neck*

ARNDT J. DUVALL, III, M.D.;† GEORGE L. ADAMS, M.D.;‡ KURT POLLAK, M.D.†
and KOMANDURI CHARYULU, M.D.‡

DURING THE PAST FIFTEEN years improvement in surgical techniques especially related to reconstruction and the use of Cobalt irradiation have provided a more effective potential in treatment of patients with head and neck cancer. In the late 1950's various centers began to initiate preoperative irradiation followed by a definitive planned surgical procedure. Powers¹ reported significant histologic changes in pathology specimens when as little as 1,500 to 3,200r of preoperative irradiation doses had been given. Biller, Davis, and Powers² reported on the survival rates of two different groups of patients with laryngeal/laryngopharyngeal cancers. One group received planned preoperative irradiation, 1,500r to 3,000r over a two to three-week period; and one group received no preoperative irradiation. They noted a difference in the survival rates which depended upon the anatomic area treated. The incidence of complications following surgery was not increased by this amount of irradiation.

In 1970, Goldman³ reported the results of fifty-five patients treated with combined therapy, utilizing

5,500 rads of Cobalt 60 over a six-week period followed by surgery. He showed an improved prognosis with this regime. Specific surgical techniques were utilized with this dosage to provide carotid artery protection.

While others have discussed theoretical benefit of preoperative irradiation followed by surgery only now have significant numbers of patients been treated by this method so that large series of results can be reported. There are still important questions which need to be answered. Does the preoperative irradiation actually alter the survival rate? Is there a lesser evidence of local recurrence? What is the optimal amount of irradiation and over what period of time should it be given so that the greatest effect on the tumor cell will occur with the least morbidity? We are reporting our experience on this large series of patients to help contribute in answering these questions.

At the University of Minnesota a prospective pilot study of combined preoperative irradiation and subsequent surgery was launched in 1964. The results of this study, along with the results of other cases managed by individual methods during this period of time, are the subject matter of this paper. The purpose of our review was to

to evaluate our protocols in the light of the analysis of these results.

Materials and Methods

The study groups included only patients whose entire treatment regime was carried out at the University of Minnesota Hospital and Veterans Administration Hospital. Patients who received a portion of their therapy elsewhere or were seen in consultation only were excluded. A diagnostic biopsy of the primary lesion or of a neck metastasis performed elsewhere did not exclude the patient from the study group.

Five hundred eighty-four patients with squamous cell carcinoma at the sites listed in Table 1 provide the group in this study. The subsequent tables will list the breakdown in two and five-year figures on the survival rates of these patients, but only the five-year figures will be used for discussion in the paper. Patients were treated by both the Department of Radiation Therapy at the University of Minnesota Hospital, the Minneapolis Veterans Hospital, and the Department of Otolaryngology between 1959 and 1969. The object of our methods was to accomplish optimal cure rates with minimal loss of function and disfigurement. A survey of adenocarcinoma has previously been reported by two of the authors (Adams and Duvall⁴). Lesions were classified according to the TNM System of the American Joint Committee on Cancer Staging and End Results as reported in 1962.^{5,6} When necessary, retrospective classification was feasible because the charts contained accurate diagrams of the tumors together with written descriptions of the primary lesions and clinically palpable cervical metastases. Patients with nonpalpable cervical metastases who were found at the time of surgery to have metastatic nodal involvement are classified with those patients who did not have cervical involvement. All patients who underwent surgical extirpation had surgery performed in the standard en bloc philosophy, as the

operation was planned prior to the administration of 4,000 rads over three to four weeks followed by the initially planned surgical procedure after a three-week rest period.

Squamous Cell Carcinoma of the Larynx

The largest number of malignant tumors in this series was squamous cell carcinoma of the larynx. Two hundred and twelve patients with squamous cell carcinoma of the larynx were treated as determinate cases. Included are glottic and supraglottic lesions extending to the aryepiglottic folds which seemed clinically to have arisen within the endolarynx. This group includes patients who had subglottic extension. There were no patients presenting with a primary subglottic tumor without involvement of the true cord. The lesions which seemed to have arisen on the epiglottis, post-cricoid area, or pyriform sinus will be discussed separately.

Stage I (T_1N_0)

These patients have a carcinoma of the larynx which is confined to one vocal cord and have normal mobility of that vocal cord. They made up approximately 25 percent of laryngeal carcinomas. There were 50 patients in this group of whom 32 are available for five-year evaluation. Twenty-four of these had irradiation therapy as a primary treatment, and eight patients underwent surgical procedures ranging from extended cordectomy to vertical hemilaryngectomy. The results were excellent in both groups (Table 2). However, four patients among those treated primarily by radiation therapy later developed a recurrence. Two of these patients required a total laryngectomy; two had a partial laryngectomy. One patient underwent a total laryngectomy but died of recurrent tumor. In the surgical group, one patient died of recurrent disease.

Stage II (T_2N_0)

This group includes patients with tumor involving both cords with normal mobility of the

cords or involving one cord with decreased mobility of that cord (Table 3). There were 51 patients in this group of whom 30 were available for five-year evaluation. It has been our policy to perform a total laryngectomy in cases of fixed cord lesions. An ipsilateral radical neck dissection with hemithyroidectomy incontinuity was done in some cases. T₂ tumors also include those which extend into the anterior commissure. When this finding was present, it was generally an indication for combined therapy. Ten patients with T₂N₀ lesions were managed by surgery only. Three died of other causes, and two died as the result of their disease. The five-year survival rate was 70 percent. Eighteen patients with T₂N₀ lesions were treated with radiation therapy only. Nine of these patients died of other causes. Nine patients who had radiation therapy only, later required surgery for recurrent tumor. Six of these nine survived five years. Persistent edema or limited cord motion following radiation therapy suggested recurrent or persistent tumor.

Both patients who underwent 4,000 tissue rads of Cobalt 60 preoperatively over a four-week period followed by surgery in three weeks survived five years.

Stage II (T₂N₀)

In this group of patients, the tumor extended from a true cord into the subglottic region or on the ventricular band (Table 4). Of the 59 patients in this group, 33 were available for five-year evaluation, the remainder from two to five years. Of the former group, twenty-four had surgery, three had radiation therapy only, and six were treated with combined therapy. Surgery included laryngectomy with ipsilateral neck dissection. Among the 24 patients who had surgery, two died of other causes. Two others died of recurrent tumor. One patient out of the three who had radiation therapy died of other causes. One died of uncontrollable disease. All of the six who had combined therapy are alive and well at five years.

Stage III (T₃N₁)

This group of patients had similar clinical findings to the previous group. However, a palpable cervical node assumed to be a metastasis was present on initial evaluation. Twelve of the patients with T₃N₁ lesions were available for five-year evaluation. Six of these patients had surgery alone, two had irradiation, and four had combined therapy. Two of the six patients who had surgery alone died of other causes, and three died

†1959-1966

current disease. One patient treated by irradiation only died of another cause, and one is alive five years but did require a laryngectomy with neck dissection. Although the number of cases is small, it appears that patients treated by the combined approach with preoperative irradiation and planned surgery have a better prognosis (Table 5).

Stage III (T_3N_2)

Three patients with T_3N_2 tumors of the larynx with fixed or bilaterally palpable metastases died of their disease.

Stage IV (T_4N_0 and T_4N_1)

There were 30 patients with lesions that would fall into the T_4 category. These large lesions extended out of the true larynx into the subglottic or paraglottic areas. Twenty-one of these patients have died, and 20 of these died of their tumor. Three of 12 patients who had radiation therapy alone, were alive two to five years. Among six patients who received planned, combined therapy, five were alive two to five years.

Posterioricoid Carcinoma

The posterioricoid region is the area of the posterior surface of the larynx, and these tumors are classified with hypopharynx carcinomas. By definition, this area extends from the posterior surface of the arytenoid cartilages and their connecting folds to the inferior surface of the cricoid. Laryngectomy is required as part of the treatment of this tumor. The tumor may not be evident on

indirect laryngoscopy. It is found by lifting the larynx anteriorly with the blade of the laryngoscope. The tumor is uncommon in our series and is generally less common in the United States than in certain areas of England and Wales. Many authors feel that a surgical procedure of large magnitude is the only advised treatment for patients with this lesion. A laryngopharyngectomy, hemithyroidectomy, and radical neck dissection are necessary, as well as an additional surgical procedure for reconstruction of a portion of the cervical esophagus. There were only seven cases of this tumor in the ten-year period. There is only one five-year survivor. He had a T_2N_0 lesion treated by irradiation and died from carcinoma of the rectum at ten years (Table 6).

Pyriform Sinus Carcinoma

Patients with carcinoma of the pyriform sinus frequently have metastases when they are first seen. The pyriform sinus should be suspected as the site of a primary tumor when a neck mass is present and there is no apparent primary evident. Small lesions in the lateral pyriform sinus usually metastasize to the deep jugular nodes early in the course of disease even before the patient has significant symptoms.

In our 55 patients treated with preoperative irradiation combined with laryngopharyngectomy, hemithyroidectomy, and ipsilateral neck dissection, a statistical analysis cannot be made from the

data. As Table 7 demonstrates, however, the patient with a large lesion with palpable cervical metastases has a poor prognosis.

Hypopharynx Carcinoma

Tumors in the pyriform sinus and postcricoid area have been discussed. The posterior wall of the hypopharynx is an area that is generally not amenable to treatment by surgery as there is insufficient cleavage of dissection; that is, the lesion ordinarily extends through the prevertebral fascia. There were 16 patients who had tumors of this area, and 15 of these were treated by irradiation therapy. In certain patients during the course of therapy, it was found necessary to reduce

the chance of aspiration pneumonitis by the judicious use of tracheostomy and gastrostomy. Four of the initial patients are still alive, and one patient has survived ten years without tumor. One patient had a small lesion amenable to surgery. He is alive at two and one-half years and requires pharyngeal dilatation.

Epiglottitis

Tumors of the epiglottitis may arise near the tip or on the laryngeal or vallecular surfaces. It is not always easy to determine whether the lesions should be classified with the base of tongue or the larynx. There were 19 patients in whom the tumor was felt to originate primarily on the epiglottitis (Table 8). Among this group of va-

*Recurrence treated by surgery.

in sized lesions, only two patients, both of whom had nodal metastases when initially seen, died of the disease. Both patients developed distant metastases. Methods of treatment included both radiation therapy and surgery.

Stomal Recurrence

Stomal recurrence following laryngectomy is a difficult problem. Kveim,⁸ in his study, showed a high correlation of stomal recurrence with preoperative tracheostomies, particularly when done more than a few days prior to the surgical procedure. There were 14 patients with stomal recurrence in this series. Eleven had primary tumors of the larynx and three had primary tumors in the piriform sinus. No direct correlation with preoperative tracheostomy could be made. In addition, there was no direct correlation with subglottic extension. There were thirteen patients who required a tracheostomy more than forty-eight hours before surgery; and nine of these patients died, and two had stomal recurrence. These patients all initially had very large lesions. There were 22 patients with subglottic extensions. Twelve

of these patients have died, and four of these patients had developed stomal recurrence. The single factor which stood out as being common in all cases was the presence of viable tumor in metastatic nodes in the pathologic specimen. Since all patients received an ipsilateral hemithyroidectomy, this was not felt to be a factor in the incidence of stomal recurrence. Only two of the patients with stomal recurrence are still alive without disease, and both are alive more than five years. One patient was treated by irradiation therapy only, and the other was treated by a wide local excision and radiation therapy. The known causes of death of the other stomal recurrences are shown in Table 9.

Squamous Cell Carcinoma of the Base of the Tongue

Tumors of the posterior one-third of the tongue, although classified with oral carcinomas, have a poorer prognosis. This is because of the poor differentiation of these tumors and the rich lymphatic supply which passes through the pharyngeal walls and into the subdigastric nodes. The patients do not seem to develop symptoms until the tumor is greater than two centimeters in size. In most series, over 50 percent of the patients with tumors in this area have palpable cervical metastases when first seen. The New York Memorial series⁹ reported a 15 percent, five-year survival rate among patients presenting with unilateral metastatic nodes, and nine percent survival rate when

*Recurrence treated by surgery.

there were bilateral metastases.

Among the 52 patients treated in our series, eleven are alive at five years, and two others are alive between two and five years (Table 10). Ten patients died from causes other than their tongue cancer; nine from other primaries (stomach, esophagus, parotid, prostate, and lungs). Radiation therapy was either given preoperatively or as the primary treatment. Surgery was reserved for a persistent tumor or for persistent cervical metastases. Irradiation is our preferred method of treatment. Tumors which cross the midline, which is not an uncommon finding, are treated only by irradiation therapy. Laterally located tumors can be treated by surgery. The extensive surgical procedure may include a laryngectomy for prevention of aspiration and/or primary surgical closure.

Tonsillar Area Carcinoma

Next to the larynx, the tonsillar area was the most common site of tumor. The term tonsillar area is used as these tumors are rarely confined to the tonsillar fossa.¹⁰ They extend onto the soft palate, and into the immediately adjacent posterior one-third of the tongue.

During the early part of this series, the treatment was generally irradiation therapy. Surgery was reserved for those patients with recurrent or persistent cervical nodes. Later in this series be-

cause the results were not satisfactory, the plan of management was changed to preoperative radiation therapy followed by surgical extirpation of the primary lesions with the cervical metastases. The original lesion was considered technically resectable. Surgery would involve ipsilateral neck dissection, partial mandibulectomy, and en bloc resection of the primary tumor. This was performed on all patients having a lesion larger than T₂. Excision of a portion of the mandible permitted primary closure in a large number of cases. Flaps were reserved for cases in which this could not be performed without undue tension on suture lines, or by compromising the line of resection.

There were 96 patients with carcinoma in the tonsillar area. In a very advanced lesion, neither surgery alone nor radiation therapy alone provided a satisfactory survival rate (Table 11). Unlike tumors in the base of the tongue where the patients frequently died from another cause, sixty of the patients died as a direct result of their tumor. Sixteen patients are alive between two and five years without recurrence.

Oropharynx Carcinoma

Patients who had tumors arising in the posterior wall of the oropharynx with extension to the lateral walls other than those in the tonsillar area were generally not amenable to treatment by surgery. Radiation therapy has been the only form

treatment in these 15 patients, and four patients are alive at five years. One patient died of other causes, and two patients had another simultaneous primary. These latter two patients have died. The remainder of the patients died as a direct result of their tumors (Table 12).

Squamous Cell Carcinoma of the Nose

There were nine patients with primary squamous cell carcinoma occurring in the nose (Table 13). The majority of these tumors were on the septum. Wide local excision was necessary; and if the tumor extended into the skin of the nose, rhinectomy was done. Although cosmetically a difficult problem, the survival rate was good. When a very wide surgical procedure was necessary, a quite socially acceptable prosthetic appliance was made for the patient. Plastic reconstruction is not a wise choice.

Nasopharynx Carcinoma

Twenty-eight patients (Table 14) with malignant tumors of the nasopharynx were treated during this period. Those patients with squamous cell carcinoma, lymphoepithelioma, or poorly differentiated squamous cell carcinoma are discussed. There appears to be a correlation with the type of tumor and the survival rate in this small series. This is noticeable in the group of patients with lymphoepithelioma. These three patients were in their early 20's and have no evidence of recurrent tumor. One of these patients required an ipsi-

lateral neck dissection followed by postoperative radiation therapy. He has been active in sports for two years since surgery. There is no evidence of recurrent tumor.

At the M. D. Anderson Hospital,¹⁰ the overall five-year survival for patients with lymphoepithelioma was 35 percent. Many pathologists feel that lymphoepithelioma is a squamous cell carcinoma with lymphocytic elements. In any case, our series showed a predilection for this particular type of tumor in younger individuals.

Treatment of these tumors has always been irradiation therapy. The lymphatic drainage is to the high posterior cervical nodes, the parapharyngeal group of nodes, and to the subdiaphragmatic node. In rare cases, the tumor can metastasize directly to the subdiaphragmatic node without involvement of the higher nodes. In this situation if the primary is controlled and cervical metastases persist, a radical neck procedure can be performed. This is not common. Patients may have involvement of the cranial nerves; usually III, V, and VI.

Three of our patients had return of function of these cranial nerves following irradiation therapy.

Palate

There were 11 patients with squamous cell carcinoma confined to the hard or soft palate (Table

15). Treatment of Stage I lesions of the soft palate has been irradiation therapy, and all the patients are alive between two and five years. Radiation therapy was used primarily because of the rich lymphatic drainage of the soft palate; and early involvement of high retropharyngeal nodes

		Surg.	1	0	1	0	0	0

Tumors occurring at the junction of the hard and soft palate were also treated by irradiation. A tumor confined to the hard palate was treated unsatisfactorily by surgery.

Carcinoma of the Paranasal Sinuses

The maxillary sinus is the most common sinus to be involved with squamous cell carcinoma (Table 16). The ethmoid sinuses are the second most common group, and carcinoma in the frontal and sphenoid sinuses is rare. Nine patients had carcinoma of the maxillary-ethmoid area, and one patient had a primary squamous cell carcinoma in the frontal sinus. The patient with frontal sinus carcinoma was treated by surgical excision of the tumor. This involved removal of the anterior and posterior walls of the sinus and the dura in proximity to the tumor.

Treatment for carcinomas of the paranasal sinuses has generally been irradiation therapy in full course followed by surgery in six weeks if there was persistent tumor present, as evidenced by repeat biopsy. A tumor was felt to be resectable if it did not extend into the parapharyngeal space as demonstrated by erosion of the posterior wall of the maxillary sinus and/or the pterygoid plates or into the posterior ethmoid cells. The advent of the polytome has been an invaluable aid in determining bony erosion. Anterior ethmoid tumors can be treated by a combined approach with neurosurgery. In our experience, this combined approach has been utilized for sarcoma (chondrosarcoma and fibrosarcoma) and squamous cell carcinoma.

The majority of patients with carcinoma of the maxilla already had a tumor extending out of the maxilla either onto the cheek, the alveolar ridge, or into the nose or onto the palate. It should be noted that palpable cervical metastases were present in five of 19 such patients, but no patient in whom the tumor was confined to the sinus had palpable cervical nodes. Ohngren's line, which divides the maxillary sinus into anterior-inferior and posterior-superior regions, has been cited as an important line of differentiation in regard to prognosis. This is probably only valid in tumors completely confined to the "maxillary box." Any extension beyond the "box" wherever its origin, denotes a poorer prognosis. The surgical procedure of choice has been radical maxillectomy. This procedure has not been as cosmetically deforming as might be anticipated when

the orbit is preserved. When there is involvement with tumor close to the orbital floor, the risk of preserving the orbital contents is too great. Maxillectomy (with or without orbital exenteration) can be performed on patients who have had heavy irradiation as the wound is "open."

Unknown Primary (The Metastatic Neck Node)

Before a patient is placed in this category, a complete evaluation including multiple biopsies of the laryngopharynx and nasopharynx has been performed. In addition, bronchoscopy, esophagoscopy, esophagram, and planograms of a suspected lesion in the lung, as well as thyroid function studies are done. Upper and lower G.I. series and I.V.P. are performed if there is any suspicion that this might be a primary site. If there is no evidence of another primary lesion, biopsy is performed with patient prepared for radical neck dissection. The "last" diagnostic procedure is biopsy.

Jesse and Neff¹² reported 10 three year survivors among twenty-two patients with squamous cell carcinoma in subdiaphragmatic nodes in patients who had an occult primary. A report on unknown primaries from the head and neck services at Memorial Hospital in New York¹³ reveals a determinate survival rate of thirty-one percent in five years when the primary was never discovered. They advised radical surgical procedure for epidermoid carcinoma and melanoma.

Table 17 shows the methods of treatment involved in these patients. Patients with immediately supraclavicular nodes have a high incidence of primaries below the clavicle and are not included in this study. Three patients had radiation therapy only, and one died in one year. The other two were alive at eight and ten years. One of

Pt.	Age	Treatment	Outcome

S.O.	69	Co ⁶⁰ 6,000 r/T, Waldeyer's ring, suprahyoid dissection	alive 4 yrs.

these had mandibular necrosis, and one required surgery. The other patients were managed by combinations of radiation and node dissection, and in only one case was a primary tumor later found. This patient had a primary tumor at the base of the tongue. The survival rates were particularly good in this limited number of patients.

Discussion

Patients with squamous cell carcinoma involving the larynx, pharynx, nasopharynx, base of the tongue, tonsillar area, nose and paranasal sinuses have been reviewed. Follow-up data and survival statistics are listed individually in tables, accounting for each patient.

Squamous cell carcinomas of the head and neck are best treated by utilizing the skills of both the otolaryngologist and the radiotherapist. Careful follow-up of patients with early laryngeal tumors treated with radiation therapy is important. A large surgical procedure is required in patients with recurrence after radiation therapy. In patients who have recurrence in the tonsillar area or hypopharynx after radiation therapy, surgery may provide palliation but does not provide satisfactory five-year survivals. "Running after" tumors is not valid. If the lesion is originally resectable, surgery should follow radiation.

The use of 4,000r of Cobalt therapy preoperatively over a three-week period followed in three weeks by surgery did not significantly increase serious complications. The most common complication after laryngeal surgery is a fistula. A secondary closure of the fistula is usually not necessary if the patient will tolerate prolonged use of a nasogastric tube along with careful cleansing of the wound. Operative mortality is extremely low. Three patients died from causes directly related to the surgery, two from myocardial infarction and one from a cerebral vascular accident.

Based on the results of this study and the results reported by others, our present treatment plan is outlined. In carcinoma of the maxilla and tonsil, elective surgery after preoperative irradiation is being substituted for irradiation followed by surgery only for recurrence.

Larynx

1. T₁—irradiation therapy
2. T₂—limited mobility but not fixed, full course irradiation—fixed or involving cartilaginous ant. commissure, irradiation and surgery.
3. T₃ and T₄—Irradiation and surgery
4. Subglottic extension—preoperative irradiation and surgery

5. Laryngeal obstruction—immediate surgery without tracheostomy followed by postoperative irradiation.

Post-cricoid

1. Preoperative irradiation
2. Surgery

Pharynx

1. Posterior pharyngeal wall—irradiation to primary and neck
2. Lateral pharyngeal wall and pyriform sinus
 - a. Preoperative irradiation to primary and neck
 - b. Appropriate resection of primary and elective neck dissection

Base of Tongue

1. Irradiation therapy, full course
2. Irradiation therapy to negative neck—5,000r
3. Irradiation therapy to positive neck—6,000r

Tonsillar Area

1. T₁N₀—irradiation, full course (6,500r-7,000r)
2. T₂N₀—irradiation, full course or preoperative irradiation and surgery (neck and primary continuity)—individual selection
3. T₂N₁, T₃, and T₄—preoperative irradiation to primary and neck (5,000r) and surgery (neck and primary discontinuity)
4. Original primary and/or neck unresectable—irradiation, full course, (Unresectability determined by extent of primary or fixed or contralateral nodes)

Soft Palate

1. Irradiation therapy, full course
2. Irradiation to neck
 - a. No palpable nodes—5,000r
 - b. Palpable nodes—6,000r

Nasopharynx

1. Irradiation therapy, full course
2. Irradiation to clinically negative neck—5,000r
3. Irradiation to positive neck—6,000r

Maxillo-ethmoid Sinuses

1. Dental extraction (when necessary)
2. Drainage procedure—Nasoantral window
3. Irradiation—6,500r-7,000r (over eight weeks)
4. Maxilloethmoidectomy if initially resectable (may require combined intra-cranial approach.)

Criteria of resectability:

- a. Posterior ethmoids free of tumor
- b. No bony erosion of posterior wall of maxillary sinus or pterygoid plates

At present we have not developed protocols for certain areas, such as the nose, either because of the variation in extent and position of the primary or because a clear method of treatment does not present itself from available data.

Conclusion

Carcinoma of the upper respiratory and deglutition areas comprise a significant proportion of malignancies. Eighty percent of the primary lesions are visible directly or indirectly by mirror examination. Therefore, detection and biopsy

should be promptly made when the patient first presents himself to the medical profession. Open biopsy of neck metastases is condemned. It should be the last, not the first, diagnostic procedure.

Our study definitely shows that regardless of the type of particular treatment, the greatest improvement that can be made in the future will be an early diagnosis.

It's the Law

Fatal Hemorrhage Following Surgery

A 30-year-old housewife was admitted to the hospital for cesarean section and hysterectomy. Twelve hours after the procedures were performed, she went into convulsions, shock and died. Her death was determined to be caused by internal hemorrhage.

The woman's husband filed suit. He claimed that the hospital nurses failed to monitor the woman's vital signs and that the woman's blood type was not kept available in the hospital blood bank.

The family further contended that the physicians negligently performed the cesarean section and hysterectomy and that the physicians failed to render proper postoperative care. The physicians argued that they exercised appropriate standards of care and that the woman was in irreversible shock when they were notified of her condition.

The hospital argued that the woman was not in irreversible shock and that the woman could have been saved by the physicians with proper care.

The jury awarded the family of this lady \$225,000. The verdict was against the hospital only, not against the attending physicians.

Gilles de la Tourette's Syndrome

International Registry

FARUK E. ABUZZAHAB, SR., M.D., Ph.D.* and FLOYD O. ANDERSON, B.A.†

THE SYNDROME OF GILLES DE LA TOURETTE, with its peculiar motor and vocal symptomatology, has fascinated medical professionals all over the world. Its etiology is obscure even after over a hundred years of observations, and only recently have its symptoms been controllable. In order to obtain case reports of the illness, an exhaustive search of the literature was conducted, and an international registry was set up. This report is based upon information consolidated from 430 published cases plus 55 case reports that have come to our attention through the international registry.

History

The first description of the syndrome, albeit sketchy, was in 1810 by Bouteille¹ in his "Treatise on Chorea." Itard² presented the case report in 1825 of the Marquise de Dampierre, then 26 years old. This influential woman had developed the symptoms of Tourette's syndrome at the age of seven and, because of coprolalia and echolalia, spent most of her long life in seclusion.

Her case was to be the classic case of Tourette's syndrome. It was reported by Roth in 1850 and again by Sandras in 1851, by Trousseau in 1873, who called it "diaphragmatic chorea," and by H. Jones in 1874. She was seen by Gilles de la Tourette, Charcot, and Mirto at the Salpêtrière in the early 1880's, and her case was mentioned in Gilles de la Tourette's 1885 analysis of nine cases entitled "A Nervous Affection Characterized by Motor Incoordination, Accompanied by Echolalia and Coprolalia."³

All of the early work was not done by the

French. In 1881 (four years before Tourette's description), Friedreich published a case report of what he called "Koordinierte Erinnerungskämpfe," which was identical with the syndrome of Gilles de la Tourette.⁴

Gilles de la Tourette, prior to 1885, had taken interest in Beard's work of 1880 on the "jumpers" of Maine, O'Brien's report on "latah" in Malaya, and Hammond's treatise on "myriachit" in Siberia. This led to his 1884 paper⁵ which collected previous observations and reported one of his own. He felt that these various illnesses were in fact the same. He reasserted this opinion in his classic paper of 1885, which proved his ability as a gifted observer and nosologist, for which the syndrome was named after him.

Some of the most significant work since 1885 includes: 1890: Jacques Catrou, another student of Charcot at the Salpêtrière, presented a detailed history and 45 case summaries in his inaugural dissertation.⁶

1899: Koester found 50 cases in a review of the literature, and presented the two cases of Tourette's syndrome diagnosed in 2500 admissions at the Universitäts Poliklinik in Leipzig.⁷

1946: Mahler reported a series of ten patients studied from one to eleven years.⁸

1948: Eduard Ascher found four cases among 9000 inpatient and 50,000 outpatient admissions to a psychiatric clinic.⁹

1961: Seignot successfully treated Gilles de la Tourette's syndrome with haloperidol.¹⁰

1961: Salmi found one case of the syndrome among 5300 children at the Education Guidance Clinic in Finland.¹¹

1966: Feild, et al., reported on seven cases diagnosed out of 1.5 million admissions to the Mayo Clinic since 1935.¹²

1967: Challas and co-workers analyzed 57 case reports in a review of the literature since 1942.¹³

1970: Snyder compared various therapies in 108 cases of Gilles de la Tourette's syndrome.¹⁴

Summary of Case Reports

Tourette's syndrome has been known variously as *maladie de tics*,¹⁵ *tic convulsif*,¹⁶ *tic impulsif*,¹⁷ *minimische Krampfneurose*,¹⁸ and other names. The following data reflect the symptoms and historical picture evident at clinical presentation.

Figure 1 graphs the ages at which the symptoms of Tourette's syndrome first appeared. Not included in it are 15 cases (less than 4% of all cases reported) where symptom onset occurred beyond the age of 20. The age of onset in fully 90% of reported cases was between three and 16 years, with over three-fourths between the ages of five and 12 years.

Figure 1

Seventy-one percent of Tourette tiqueurs are males, although the classic patient was a woman, first described by Itard in 1825 and by four other authors, including Gilles de la Tourette himself, in the next 65 years. The frequencies of symptoms are presented in Table 1. Motor symptoms include mainly tic-like movements, often coordinated and fluctuating. Most commonly the facial mimic muscles are involved. Grimacing, blinking and other facial tics are reported in 92% of the patients. Arm tics occurred in 78%, while only 54% had gait disturbance or frank leg tics. Head jerks and other neck tics appeared in 53% and, although several authors thought that eye-blinking was the most frequent motor symptom, it was mentioned in only 31% of the case reports. Involuntary imitation of movements, called echopraxia or echokinesis, was present in only 9% of these cases.

Vocal symptoms reported include various inarticulations, such as barks and monosyllables; coprolalia, or involuntary obscene exclamations;

TABLE 1
Frequency of Symptoms

Motor Symptoms:	
Facial tics	92%
Arm tics	78%
Leg tics	54%
Neck tics	53%
Eye tics	31%
Vocal Symptoms:	
Inarticulations	65%
Coprolalia	58%
Echolalia	23%

and echolalia, or involuntary repetition of the spoken or written word. Inarticulations were generally the first vocalizations to appear, and they were reported in two-thirds of the patients. Coprolalia, which in the presence of tics is pathognomonic of Tourette's syndrome, occurred in 58%, while echolalia was reported in only one-fourth. One or more vocal symptoms occurred in over 90% of the patients.

Psychopathology was present in 33% of the cases. The vast majority of these were various neuroses classified as obsessive-compulsive. Frequently encountered were arithmomania, (repetitive counting) folie du doute and delire du touche (abnormal doubts, abnormal desire to touch).

Electroencephalographic studies were done on 102 patients, with 45 producing abnormal results. Figure 2 depicts the distribution of scores on the Wechsler Intelligence Scale for Children. Forty-five full scale scores were reported, with almost normal distribution except for a preponderance of scores in the 110-119 range. In 66 case reports, intelligence was described as "average," with 26 "above average" and 14 "below average."

A family history of neuroticism was found in 57%, but this figure is misleading, since positive findings were of common and unrelated problems,

Figure 2

and rarely was there any extrapyramidal tract involvement. Only in three cases was another family member a Tourette tiqueur.

Among the many possible causes that have been suggested for Tourette's syndrome are birth damage, early traumatic events or infectious diseases, and family dynamics. Birth abnormalities and abnormal growth and development were reported in only 15% of patients, and none of these were frequent enough to make one suspect any connection with the development of the illness. On the other hand, a precipitating event was described in 161 cases or 37%. Most frequently associated with symptom onset were infections and various traumatic episodes, with no significant incidence of encephalitis or probable encephalitis (3%).

There is evidence that family dynamics may contribute if one or both parents are strict or dominating, or if the domestic situation is in other ways hostile. This was the case with 135 patients. Such data were seldom reported by early investigators.

Cross Cultural Analysis

When the 485 cases were divided into groups reflecting their national origin, as is seen in Table 2, there were five groups (from the United States, France, the United Kingdom, Italy and Germany) with a sufficient number of patients so that significant statistical comparisons could be made. Each group was analyzed against all cases not in that group by the Chi Square method (Graph in Figure 1).

As is evident from Figure 1, the cases from the United States have an earlier age of onset than the European ones, and this difference is statistically significant.

There were few significant deviations in motor symptoms between groups and the male-female ratio also showed an excellent fit. The high correlations between samples in all but a few instances

were impressive. The Italian sample showed a significantly higher frequency of eye tics, while the French showed significantly fewer. More neck tics were observed in the United States sample and fewer in the French.

A similarly close fit was not found with the copro- and echophenomena, however. The British group displayed significantly less echophenomena, while the other vocal phenomena fit closely. On the other hand, the French group showed much more echokinesis than expected. Many of the patients in earlier reports from France presented this symptom, which was described in the French literature of the early 1880's. Perhaps the novelty of this fascinating symptom led to its frequent diagnosis.

Coprolalia was found to occur in the United States with a significantly higher frequency than elsewhere, although other vocal symptoms occurred with expected frequencies. Despite the many statistically significant differences found in other groups, the German sample corresponded very well and could be described as the typical group.

TABLE 3
Cross-Cultural
Symptom Differences*

United States	Younger age at onset More neck tics More coprolalia
France:	Less neck tics Less eye tics More echokinesis
Germany:	No significant differences
United Kingdom:	Less echophenomena
Italy:	More eye tics

Results of Therapy

Table 4 gives the results of the most frequently used modes of treatment. In the 430 cases in the literature, there were just under 600 therapeutic trials, many patients being given more than one type of treatment.

Different types of psychotherapy were frequently employed with Gilles de la Tourette's patients. Forty-five percent were described as "improved," but only 12% for more than six months. Behavioral modification therapy produced six-month "improvement" in 25% of trials, but had a 75% failure rate.

The results of chemotherapy are difficult to evaluate due to the simultaneous administration of different classes of drugs. The benefit of halo-

peridol is plain. Fully two-thirds of its therapeutic trials gave a greater than six-month "improvement," and 89% of trials produced some "improvement." The other antipsychotic tranquilizers produced "improvement" in 48% of trials, with 22% giving long-term "improvement."

Other modes of therapy not tabulated, many of them now known to be undesirable, do not seem to be valuable in the control of Tourette symptoms. These miscellaneous therapies include chiropractic treatment, lysergic acid diethylamide (LSD), fever therapy, hygiene, flogging, strictness, megavitamins, leeches and muscle relaxants.

It is of note that 14 patients (3.3%) had spontaneous remissions at six-month follow-up.

Comment

Over two-thirds (71%) of Tourette patients in our sample were males, comparing closely to the ratios observed by Gilles de la Tourette and subsequent investigators. A similar preponderance of males is seen with simple tics. The key clinical features leading to the diagnosis of Tourette's syndrome in this study were childhood onset (90.5% between three and 16 years) of more or less generalized motor tics involving most frequently the face (98%) and the upper extremities

(78%). One or more vocal symptoms, either inarticulations, coprolalia or echolalia, were present in 93% of cases at some time during the course of the illness. In the vast majority of cases, the vocal symptoms led to the diagnosis, although coprolalia, considered pathognomonic of the syndrome, occurred in just 68% of the cases.

The syndrome's course is typified by remissions and exacerbations with fluctuating symptomatology. Spontaneous remissions of six months or more were observed in only 14 reported cases (3.3%).

There are no diagnostic tests of value currently. However, Messiha, et al.¹⁹ reports that levels of urinary catecholamines, notably dopamine, fluctuated directly with the severity of symptoms in a patient with Tourette's syndrome. Earlier, Snyder, et al.¹⁴ hypothesized that hypersecretion of dopamine in the corpus striatum could be at least part of the pathophysiological picture, given the startling improvement seen with haloperidol therapy.

The cross-cultural comparison of case histories showed that the main features of the syndrome are similar, with some variation in symptom expression as summarized in Table 3.

The statistically significant variation in symp-

Spontaneous Remission 14 (representing 3.3% of patients)

Analysis of various therapies reported in 430 case histories of Gilles de la Tourette's syndrome surveyed in the literature (often several therapeutic trials were given to the same patient). (1) "Sedatives": ethanol, chloral hydrate, ethchlorvynol, bromides, barbiturates, meprobamate, chlordiazepoxide, diazepam, oxazepam, hydroxyzine, methaqualone, arsenic, paraldehyde. (2) "Antipsychotic tranquilizers": reserpine, rauwolfia alkaloids, chlorpromazine, promazine, trifluorpromazine, thioridazine, prochlorperazine, trifluoperazine, chlorprothixene, fluphenazine, perphenazine, thiothixene, piperacetazine, promethazine. (3) "Antidepressants": imipramine, amitriptyline, nortriptyline, doxepin, protriptyline, isocarboxazid, phenelzine, iproniazid. (4) "CNS stimulants": amphetamine, d-amphetamine, methamphetamine, methylphenidate. (5) "Anticonvulsants": Diphenylhydantoin, primidone, trimethadione, ethosuximide, paramethadione. (6) "Antiparkinsonians": belladonna alkaloids, trihexyphenidyl, bethtropine mesylate, orphenadrine, diphenhydramine, L-dopa, amantadine.

tom expression could represent the bias of authors from particular cultural settings. One difficulty in our attempts at cross-cultural analysis was that only 48 cases (9.9%) were reported from countries other than the United States, France, the United Kingdom, Italy and Germany, most of the others being Eastern European. The higher incidence of case reports from the Western nations might reflect eagerness to publish rather than an actual higher incidence of the illness.

The comparison of different treatment regimes

used with these patients shows that haloperidol is superior to any other treatment, and must be considered the treatment of choice in Gilles de la Tourette's syndrome. The antipsychotic tranquilizers have some value, but the efficacy of psychotherapy and other regimes is questionable.

An international registry has been founded and physicians are encouraged to contribute their clinical observations by contacting the senior author of this article.

Capillary-viritis Syndrome

Eppinger in 1938 first introduced the term "capillary syndrome in viral infections" in connection with protein leakage into the tissues. Injury to the capillary system and change in its physiologic function have been observed as sequelae in several types of viritis. Increased fragility with petechiae and purpura are commonly present. Permeability is increased with loss of a significant amount of plasma through the walls of these minute vessels.

Sokoloff expressed the belief that the capillary changes are of special importance in such diseases as viral hepatitis, poliomyelitis, smallpox, measles, primary atypical pneumonia, mumps with orchitis, and rabies. There is, he suggested, a more ready invasion of the virus particles after damage to the vascular walls. He also suggested that the citrus flavonoids, which contain vitamin P or capillary permeability factor, minimize the injury to the wall and may reduce the degree of invasiveness by the viral infection.*

AUTHOR'S NOTE: Conversely, the most conspicuous degree of decreased capillary permeability occurs in myxedema.

Parkinson's Disease

Modern Treatment

EDUARDO TOLOSA, M.D.*

FOLLOWING THE OBSERVATIONS by Ehringer and Hornykiewicz¹⁸ that dopamine is deficient in the striatum of patients with Parkinson's disease, L-Dopa was introduced in the treatment of this disorder. Since the initial reports by Cotzias et al.¹³ in 1967, numerous clinical trials have confirmed its effectiveness.^{10,54,34} Approximately 60% of the treated patients have shown a marked improvement in all cardinal features of the disease—rigidity, bradykinesia and tremor. The average daily dose of L-Dopa required for an optimal anti-parkinsonian effect is usually between four and six Gm. The intervals of administration vary with each patient but are usually short (two to four hours). The optimal therapeutic effect is usually achieved within one to three months. Among patients on chronic L-Dopa therapy we have found several patterns of response to the drug⁵² (Figure 1) and not infrequently this clinical response may change in a patient from a sustained improvement initially, to a short or irregular duration of effect of each dose later on. The major side effects consist of nausea and vomiting, postural hypotension, cardiac arrhythmias, abnormal involuntary movements, and psychiatric disturbances.³³ Abnormal involuntary movements occur in more than 60% of the patients after one year of treatment¹ and are one of the factors that most commonly limit the administration of optimal therapeutic doses.³² The type of movement is variable but tends to show some stereotyped characteristics for each patient. Any muscle group may be involved but the ones affecting the orobuccofacial (Figure 2) and the truncal musculature are frequently very disabling. They may occur at the time of best anti-parkinsonian effect of the drug, but in some patients we have observed them when marked parkinsonian features are present, making it difficult to establish whether the patient

is under or overdosed. In this context we have found the determination of plasma-dopa concentrations to be very useful.⁵³

Although L-Dopa has been a major step forward in the treatment of Parkinson's disease, this form of therapy has certain shortcomings. The most significant ones are: a long induction time for optimal effects, toxic side effects and a short or irregular response in some patients. About 10 to 15 percent of the cases obtain a poor results because of intolerance to the drug or because of only minimal improvement for reasons that are unknown. In an attempt to overcome these problems, drugs that can potentiate the therapeutic

Fig. 1—Patterns of clinical response to L-Dopa among patients on chronic L-Dopa therapy. Upper curve: sustained clinical response through the day. Middle curves: short or irregular duration of effect of each L-Dopa dose. Lower curve: little improvement to repeated doses of L-Dopa. Curves of disability are based on hourly examinations of patients during 16 hour intervals. Disability scale represents the sum of scores (O=absent, 3=marked) for tremor, rigidity, bradykinesia and gait impairment.

Fig. 2—L-Dopa induced abnormal involuntary movements. *Left:* Facial expression before L-Dopa administration. *Right:* Irregular dystonic contraction of the facial muscles when talking, two hours after a dose of 1 gm. of L-Dopa.

Fig. 3—Schematic diagram illustrating the main steps of dopamine (DA) metabolism in a dopaminergic synapse. Inhibition of MAO (monoamine oxidase) and COMT (catechol-O-methyl transferase) theoretically may increase the amount of DA at the receptor site. Amphetamine-like drugs stimulate the release of extra-granular, free DA. Anticholinergic agents and the tricyclic antidepressants are capable of blocking the re-uptake of DA by the nerve ending, potentiating the action of endogenously released DA.

effect of L-Dopa and reduce its undesirable side effects have been sought.

The effectiveness of L-Dopa in Parkinson's disease is thought to result from its ability to cross the "blood-brain-barrier" and increase the amount of dopamine in the striatal regions.¹² This effect can be augmented theoretically by drugs that inhibit the peripheral breakdown of L-Dopa (dopa decarboxylase inhibitors), making more amino-acid available to the brain or by drugs that presumably increase the concentration of dopamine at the receptor site by influencing monoamine metabolism at the synaptic level (Figure 3). Such drugs may either stimulate the release of extra-granular, free dopamine at the nerve endings (amphetamines), block some metabolic pathway in the central degradation of dopamine (MAO inhibitors) or inhibit the re-uptake of dopamine by the nerve terminals (tricyclic antidepressants).

Monoamine Oxidase Inhibitors

These antidepressant drugs were found to be effective in the treatment of Parkinson's disease when given with L-Dopa by Birkmayer and Hornykiewicz⁸ in 1962. Others² have noted a modest anti-parkinsonian effect of these compounds when added to anti-cholinergic drugs or even when administered alone. Their action can be related to the experimental observation that proniazid causes an apparent rise in brain catecholamines, specifically of hypothalamic noradrenaline (NA) and striatal dopamine (DA)¹⁵ but Bernheimer et al.⁶ found no increase in dopamine concentration in brains of Parkinson's patients who had received MAO inhibitors for several months. Hypertensive crises have been reported in patients on L-Dopa receiving MAO inhibitors.²⁸ In view of the fact that they produce only mild additional beneficial effects, MAO inhibitors should be avoided in patients on L-Dopa therapy.

Catechol-o-methyl Transferase Inhibitors

Dopa, DA, and other monoamine metabolites like 3,4-dihydroxyphenylacetic acid (DOPAC) and 3,4-dihydroxymandelic acid (DOMA) are o-methylated by catechol-o-methyl transferase (COMT). By blocking these pathway more dopamine can theoretically be made available at the dopaminergic receptors. If o-methylated products of dopa and dopamine are responsible for some of the L-Dopa induced side effects, these could be suppressed by administering COMT inhibitors. Ericson has reported reduction of the major parkinsonian signs as well as of some of the toxic effects of L-Dopa in 10 parkinsonian patients by administering N-butylgallate in association with L-Dopa.¹⁹

Amantadine Hydrochloride

The beneficial effects of this agent on Parkinson's disease were first reported by Schwab, et al.⁴⁴ in 1969. Its efficacy has now been confirmed in several double-blind and non-blind trials.^{25,29,37} Little is known about its mode of action. A dopamine releasing effect, similar to the one of amphetamine, has been demonstrated experimentally,²⁶ and in rats, an increased synthesis and release of dopamine in the striatum has been observed after amantadine treatment.⁴³ This drug has also been shown to block the re-uptake of NE and DA into the nerve endings in rat brains, but only when large, unphysiological doses are administered.²² Rinne et al.⁴⁰ have shown that amanta-

dine does not alter the endogenous concentration of DA, NA and HVA in the rat brain. The addition of amantadine hydrochloride (Symmetrel) to L-Dopa in the management of Parkinson's disease is of questionable value. Rinne, et al.⁴¹ found no improvement when adding amantadine to patients on L-Dopa therapy and side effects like nausea and vomiting were increased by the combined treatment, but others have indicated that the combined use of these drugs might be useful in cases when the maximum tolerated dose of L-Dopa is small.²⁵ Fehling²¹ using a double-blind cross-over technique has reported a modest improvement in a group of 24 parkinsonian patients on optimum L-Dopa dosage. Symmetrel is administered in doses of 100 mg. two to three times a day. Its toxic side effects are rare and include mental confusion, visual disturbances and livedo reticularis.

Tricyclic Antidepressants

In 1959 Sigwald et al.⁴⁶ treated ten patients with Parkinson's disease with two derivatives of iminodibenzol (imipramine and 8307 RP) and found a striking improvement in their bradykinesia, far beyond the antidepressive effect of the drugs. Since then other reports have confirmed the antiparkinsonian effect of imipramine as well as of desmethylinipramine.^{16,24,30,39,50} This effect could be related to the findings by Ross and Renyi⁴² and Snyder et al.⁴⁷ of a strong inhibitory effect of imipramine and desimipramine on the uptake of catecholamines in the rat brain, though much more pronounced in norepinephrine areas than in the dopaminergic corpus striatum. Still the mechanism of action of these compounds might be derived primarily from their anticholinergic properties.¹⁷

No firm documentation is available on the effect of adding tricyclic antidepressants to L-Dopa in the treatment of Parkinson's disease, but it is a common observation that adding imipramine or amitriptyline, 10 to 20 mg. four times a day to the L-Dopa regime may produce an improvement in some patients.

Amphetamines and Related Compounds

Thirty years ago Solomon et al.⁴⁸ reported on the therapeutic value of amphetamines in Parkinson's disease. This effect, as well as the usefulness of the combination of amphetamines plus L-Dopa in some patients recently has been confirmed by others.⁹ Amphetamine is a potent sympathomi-

metic drug and its antiparkinsonian effects are believed to be exerted by its stimulating effect on the extragranular, free catecholamines at the nerve endings. Coyle and Snyder¹⁴ have also shown experimentally that both d- and l- amphetamines are potent inhibitors of DA uptake by striatal synaptosomes of the rat brain. This effect would potentiate the action of endogenously released dopamine. Dextroamphetamine (Dexedrin) in doses of 5 mg twice a day, desoxyephedrine (Desoxyn) 2.5 mg twice daily or methylphenidate (Ritalin) 5 mg, two or three times a day can be employed.

Anticholinergic Drugs

Since the original observation, 100 years ago, by Charcot, of the beneficial effect of atropine on Parkinson's disease the anticholinergic drugs have been the treatment of choice for this disease until recently. They can produce a modest improvement, mainly of tremor and rigidity, and in many patients, they have a synergistic effect with L-Dopa.^{27,54} Their mechanism of action is disputed. A balance between dopamine and acetylcholine has been proposed as necessary for an adequate function of the striatal structures in man. In Parkinson's disease the reduction of striatal dopamine would produce an undesirable cholinergic dominance. Anticholinergic drugs would restore this balance by decreasing the amount of striatal acetylcholine.^{3,35} The anti-parkinsonian effect of these compounds, though, has not been found to be related to their anticholinergic potency.^{20,23} Recently, Coyle and Snyder¹⁴ have reported that the anticholinergic drugs are also powerful inhibitors of the uptake of DA at the endings of striatal dopaminergic neurons and this could well represent their main mechanism of action. The available anticholinergic agents have virtually similar pharmacological actions. Side effects due to peripheral cholinergic blockade such as dryness of the mouth, blurred vision, anhydrosis and urinary retention are common, and occasionally hallucinosis or a toxic confusional state may occur.

In our experience, trihexyphenidil hydrochloride (Artane), 2 mg. two to three times a day, or bztropine mesylate (Cogentin), 1 mg. three to four times a day have proved very useful adjuncts to L-Dopa therapy, but some patients respond better to other derivatives.

Dopa Decarboxylase Inhibitors

Orally administered L-Dopa is rapidly metabolized in the gut, blood and body tissues, mainly through O-methyl and decarboxylation pathways and only a small amount of L-Dopa can be detected in plasma. In an attempt to make large amounts of L-Dopa available to the central nervous system, inhibitors of dopa decarboxylase with limited capacity to cross the "blood-brain-barrier" have been administered concomitantly with L-Dopa.⁵ One of these compounds, RO 4-4602, a serylhydrazine derivative of trihydroxybenzyl has been shown experimentally to accentuate marked the L-Dopa induced accumulation of dopamine in rat brain, specifically in the striatal regions.³ Consequently smaller amounts of L-Dopa are needed when given with RO 4-4602 to increase cerebral dopamine. In man, Bianchini et al.⁷ have shown that treatment with MK-486 (alpha-methyl dopa hydrazine), a newly synthesized inhibitor of peripheral aromatic l-aminoacid decarboxylase prior to the administration of C¹⁴-L-Dopa will reduce plasma and urinary dopamine, and markedly reduce the excretion of DOPAC, an acid metabolite of dopamine. This strongly suggests that MK-486 inhibits peripheral decarboxylation of L-Dopa in man. Therefore by using a dopa decarboxylase inhibitor, some of the common side effects of L-Dopa which are presumed to be due to the adrenergic activity of its peripheral metabolites can be avoided. Considerable experience exists now in Europe^{45,51} and Canada⁴ with RO 4-4602, and MK-486 is presently the subject of several clinical trials in the U.S. and England. The few reports available on the value of the combined L-Dopa-MK-486 therapy over L-Dopa alone^{11,31,36} indicate that the salient features of the former are: (a) 60 to 70% reduction of the L-Dopa dose; (b) rapid induction of optimal therapeutic effects; (c) marked reduction of gastrointestinal and cardiovascular side effects and (d) the incidence of severity of central side effects—abnormal involuntary movements and mental disturbances—is essentially not altered.

Recently a double blind, controlled study comparing the effect of combined L-Dopa-MK-486 versus L-Dopa alone was conducted at the University of Minnesota and preliminary analysis of the results seem to corroborate the above mentioned advantages. By using a dose ratio of L-Dopa to MK-486 of 10 to one, the dose of

Dopa can be reduced by approximately 70%, though some variability exists among different patients. As can be seen in Figure 4 plasma dopa concentrations above $\mu\text{g/ml}$ can be obtained after a dose of L-Dopa as small as 125 mg. when administered with 12.5 mg of MK-486. Nausea and vomiting have been reduced to a minimum and no clinical or biochemical abnormalities related to MK-486 have been detected among our patients.

Fig. 4—Mean plasma dopa concentrations ± 1 S.D. following a 1250 mg. dose of L-Dopa (two determinations \circ) and after a dose of 125 mg of L-Dopa plus 12.5 mg of MK-486 (L-alpha-methyldopa hydrazine) (two determinations \bullet).

The decision whether to add any other anti-parkinsonian drug to the L-Dopa regime depends on the response of the patient to the amino acid. In cases in which a full and sustained improvement is obtained with the administration of L-Dopa alone it does not seem necessary to add any other therapeutic agent, with its potential unpleasant side effects. Not uncommonly, though, the therapeutic effect of L-Dopa, with or without

dopa decarboxylase inhibitors, is not complete. Here, some of the agents outlined above can be used as adjuncts to L-Dopa therapy. Of this the anticholinergic drugs are the ones that seem to have the best potentiating effect. Amantadine or one of the tricyclic antidepressants may prove better in some patients.

Since no clinical or biochemical parameters are available which indicate to which drug or combination of drugs a patient might respond better, the choice of an additional drug is made on the basis of the clinical picture, the presence or absence of certain side effects and the physician's familiarity with these different agents. The individual responses to these drugs varies and an effort on the physician's, as well as on the patient's part, should be made in an attempt to find which combination of drugs produces the maximum relief of parkinsonian signs with a minimum of side effects.

Conclusions

The finding of a reduced dopamine concentration in the striatum of patients with Parkinson's disease prompted the introduction of L-Dopa in the treatment of this disorder. L-Dopa has been confirmed in repeated clinical trials as the most potent anti-parkinsonian agent available. Amantadine hydrochloride, the anticholinergic drugs, amphetamines and the tricyclic antidepressants have proved useful adjuncts to the L-Dopa regime. The newly introduced dopa decarboxylase inhibitors are encouraging since they markedly reduce some complication of L-Dopa therapy and have so far not shown any toxicity of their own.

Modern anti-parkinsonian agents have proved strikingly successful but have also made the treatment of Parkinson's disease more difficult and have made an understanding of the basic biochemistry of the biogenic amines in the central and peripheral nervous system necessary for an adequate interpretation of their effects and their adverse reactions.

Continuing Education Medical Dates June-July, 1973

June 14—**Clinical Electroencephalography**, American Electroencephalographic Society. 8th Annual Continuation Course, Statler Hilton Hotel, Boston, Mass. Course will emphasize practical problems of interpretation for clinical diagnosis. Registration Information: Donald W. Klass, M.D., EEG Course Director, Mayo Clinic, 200 First St., S.W., Rochester, Minn. 55901.

June 22—**Second Annual Headwaters Clinical Conference**, Rutgers Birchmont Lodge, Bemidji, sponsored jointly by Bemidji Hospital & medical staff. Subjects include the central nervous system, chest, abdominal trauma & acute psychiatric manifestations of systemic disease.

July 20—**Minnesota Surgical Society**, Duluth. Secretary: James J. Mongé, M.D., Duluth Clinic, Ltd., 205 W. Second St., Duluth, 55802. Topic: Some Facets of Burn Therapy.

Integument!

Skin—the human integument covers us, defines us, protects us. But skin is subject to cuts, burns, abrasions. And infections. Neosporin Ointment fights infection by providing broad antibacterial action against susceptible skin invaders. It contains antibiotics that are rarely used topically, reducing the risk of sensitization.

INDICATIONS: Therapeutically, used as an adjunct to appropriate systemic therapy for topical infections, primary or secondary, due to susceptible organisms, as in:

- infected burns, skin grafts, surgical incisions, otitis externa
- primary pyodermas (impetigo, ecthyma, sycosis vulgaris, paronychia)
- secondarily infected dermatoses (eczema, herpes, and seborrheic dermatitis)
- traumatic lesions, inflamed or suppurating as a result of bacterial infection.

Prophylactically, the ointment may be used to prevent bacterial contamination in burns, skin grafts, incisions, and other clean lesions. For abrasions, minor cuts and wounds accidentally incurred, its use may prevent the development of infection and permit wound healing.

CONTRAINDICATIONS: Not for use in the external ear canal if the eardrum is perforated. This product is contraindicated in those individuals who have shown hypersensitivity to any of the components.

PRECAUTION: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.

Complete literature available on request from Professional Services Dept. PML.

NEOSPORIN[®] Ointment

(POLYMYXIN B-BACITRACIN-NEOMYCIN)

Each gram contains: Aerosporin[®] brand Polymyxin B Sulfate 5,000 units; zinc bacitracin 400 units; neomycin sulfate 5 mg. (equivalent to 3.5 mg. neomycin base); special white petrolatum q.s. In tubes of 1 oz. and ½ oz. and ¼ oz. (approx.) foil packets.

Wellcome

Burroughs Wellcome Co.
Research Triangle Park
North Carolina 27709

What's in it for her?

All steroid molecules are not the same...in their activity. In prescribing birth-control pills, estrogen/progestogen activity is more important than milligrams. The woman's hormone profile often indicates the activity best for her.

ethinyl estradiol/50 mcg

mestranol/100 mcg.

ethynodiol diacetate/1 mg.

ethynodiol diacetate

Typical characteristics of the "balanced" profile

- normal menses
- well-rounded breasts
- clear complexion
- normal figure with normal secondary sex characteristics
- normal cytohormonal pattern

This "center spectrum" pill has had excellent user acceptance for over seven years.

Ovulen®

Available in 20-, 21- and 28-pill schedules
Each white tablet contains: ethynodiol diacetate 1 mg./mestranol 0.1 mg.
Each pink tablet in Ovulen-28® is a placebo containing no active ingredients

for the majority of women...
when centrally balanced
activity is preferred

Typical characteristics of the slightly hyper-estrogenic profile

- heavy flow
- large breasts, sometimes fibrotic; nipples well pigmented
- very feminine appearance, occasionally short
- premenstrual syndrome, fluid retention
- tendency to uterine fibroids
- high pyknotic index

This formulation, which has less estrogenic activity and a moderate progestogenic dominance, may be a good beginning.

**Typical characteristics
of the hypoestrogenic
or androgenic profile**

- scanty menses
- small breasts
- thin, often tall,
sometimes asthenic
- possibly masculine
appearance
- acne, hirsutism
- low sexual motivation
- thin vaginal lining,
tendency to vaginitis
and dyspareunia

This pill has a relatively weak and unique* progestogen with inherent estrogenicity. Clinically, just as in animal studies, it appears not to possess antiestrogenic and androgenic activity.

Enovid-E®

Available in 20- and 21-pill schedules
Each tablet contains: norethynodrel
2.5 mg./mestranol 0.1 mg.

**a clear choice for women
when estrogen dominance
and no androgenic activity
are preferred**

*Of all the progestogens, norethynodrel most resembles the molecular structure of the estrogens. It has the weakest progestational activity of any progestogen in a combination pill.

Demulen®

in 21- and 28-pill schedules
Each tablet contains: ethynodiol
0.1 mg./ethinyl estradiol 50 mcg.
Each tablet in Demulen-28® is a
placebo containing no active ingredients.

**limited to most women
low estrogenic activity
moderate progestogen
activity are preferred**

Ovulen®

Each white tablet contains:
ethynodiol diacetate 1 mg./mestranol 0.1 mg.

Each pink tablet in Ovulen-28® and Demulen-28® is a placebo, containing no active ingredients.

Actions—Ovulen and Demulen act to prevent ovulation by inhibiting the output of gonadotropins from the pituitary gland. Ovulen and Demulen depress the output of both the follicle-stimulating hormone (FSH) and the luteinizing hormone (LH).

Special note—Oral contraceptives have been marketed in the United States since 1960. Reported pregnancy rates vary from product to product. The effectiveness of the sequential products appears to be somewhat lower than that of the combination products. Both types provide almost completely effective contraception.

An increased risk of thromboembolic disease associated with the use of hormonal contraceptives has now been shown in studies conducted in both Great Britain and the United States. Other risks, such as those of elevated blood pressure, liver disease and reduced tolerance to carbohydrates, have not been quantitated with precision.

Long-term administration of both natural and synthetic estrogens in subprimate animal species in multiples of the human dose increases the frequency of some animal carcinomas. These data cannot be transposed directly to man. The possible carcinogenicity due to the estrogens can be neither affirmed nor refuted at this time. Close clinical surveillance of all women taking oral contraceptives must be continued.

Indication—Ovulen and Demulen are indicated for oral contraception.

Contraindications—Patients with thrombophlebitis, thromboembolic disorders, cerebral apoplexy or a past history of these conditions, markedly impaired liver function, known or suspected carcinoma of the breast, known or suspected estrogen-dependent neoplasia and undiagnosed abnormal genital bleeding.

Warnings—The physician should be alert to the earliest manifestations of thrombotic disorders (thrombophlebitis, cerebrovascular disorders, pulmonary embolism and retinal thrombosis). Should any of these occur or be suspected the drug should be discontinued immediately.

Retrospective studies of morbidity and mortality conducted in Great Britain and studies of morbidity in the United States have shown a statistically significant association between thrombophlebitis, pulmonary embolism, and cerebral thrombosis and embolism and the use of oral contraceptives. There have been three principal studies in Britain^{1, 3} leading to this conclusion, and one⁴ in this country. The estimate of the relative risk of thromboembolism in the study by Vessey and Doll³ was about sevenfold, while Sartwell and associates⁴ in the United States found a relative risk of 4.4, meaning that the users are several times as likely to undergo thromboembolic disease without evident cause as nonusers. The American study also indicated that the risk did not persist after discontinuation of administration and that it was not enhanced by long-continued administration. The American study was not designed to evaluate a difference between products. However, the study suggested that there might be an increased risk of thromboembolic disease in users of sequential products. This risk cannot be quantitated, and further studies to confirm this finding are desirable.

Discontinue medication pending examination if there is sudden partial or complete loss of vision, or if there is a sudden onset of proptosis, diplopia or migraine. If examination reveals papilledema or retinal vascular lesions medication should be withdrawn.

Since the safety of Ovulen and Demulen in pregnancy has not been demonstrated, it is recommended that for any patient who has missed two consecutive periods pregnancy should be ruled out before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule the possibility of pregnancy should be considered at the time of the first missed period.

A small fraction of the hormonal agents in oral contraceptives has been identified in the milk of mothers receiving these drugs. The long-range effect to the nursing infant cannot be determined at this time.

Precautions—The pretreatment and periodic physical examinations should include special reference to the breasts and pelvic organs, including a Papanicolaou smear since estrogens have been known to produce tumors, some of them malignant, in five species of subprimate animals. Endocrine and possibly liver function tests may be affected by treatment with Ovulen or Demulen. Therefore, if such tests are abnormal in a patient taking Ovulen or Demulen, it is recommended that they be repeated after the drug has been withdrawn for two months. Under the influence of progestogen-estrogen preparations pre-existing uterine fibromyomas may increase in size. Because these agents may cause some degree of fluid retention, conditions which might be influenced by this factor, such as epilepsy, migraine, asthma, cardiac or renal dysfunction, require careful observation. In breakthrough bleeding, and in all cases of irregular bleeding per vaginam, nonfunctional causes should be borne in mind. In undiagnosed bleeding per vaginam adequate diagnostic measures are indicated. Patients with a history of psychic depression should be carefully observed and the drug discontinued if the depression recurs to a serious degree. Any possible

Demulen®

Each white tablet contains:
ethynodiol diacetate 1 mg./ethinyl estradiol 50 mcg.

influence of prolonged Ovulen or Demulen therapy on pituitary, adrenal, hepatic or uterine function awaits further study. A glucose tolerance has been observed in a significant percentage of patients on oral contraceptives. The mechanism of this decrease is obscure. For this reason, diabetic patients should be carefully watched while receiving Ovulen or Demulen therapy. The age of the patient constitutes no absolute limiting factor, although treatment with Ovulen or Demulen may mask the onset of the climacteric. The pathologist should be advised of Ovulen or Demulen therapy when relevant studies are submitted. Susceptible women may experience an increase in blood pressure following administration of contraceptive steroids.

Adverse reactions observed in patients receiving oral contraceptives—A statistically significant association has been demonstrated between use of oral contraceptives and the following adverse reactions: thrombophlebitis, pulmonary embolism, cerebral thrombosis.

Although available evidence is suggestive of an association, the relationship has been neither confirmed nor refuted for the serious adverse reactions: neuro-ocular lesions, e.g., retinal thrombosis and optic neuritis.

The following adverse reactions are known to occur in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal disturbances (such as abdominal cramps and bloating), breakthrough bleeding, spotting, change in menstrual flow, amenorrhea during and after treatment, edema, chloasma or melasma, breast changes (tenderness, enlargement and secretion), change in weight (increase or decrease), changes in cervical erosion and cervical secretions, suppression of lactation when given immediately post partum, cholestatic jaundice, migraine, rash (allergic), rise in blood pressure in susceptible individuals and mental depression.

Although the following adverse reactions have been reported in users of oral contraceptives, an association has been neither confirmed nor refuted: anovulation post treatment, premenstrual syndrome, changes in libido, changes in appetite, cystitis-like syndrome, headache, nervousness, dizziness, fatigue, backache, hirsutism, alopecia, scalp hair, erythema multiforme, erythema nodosum, hemiparesis, eruption and itching.

The following laboratory results may be altered by the use of oral contraceptives: hepatic function: increased sulfobromophthalein retention and other tests; coagulation tests: increase in prothrombin time, VII, VIII, IX and X; thyroid function: increase in PBI and butanol-soluble protein bound iodine, and decrease in T₃ uptake values; meloxic acid test and pregnanediol determination.

Medical Circles

*He drew a circle that shut me out—
Heretic, rebel, a thing to flout
But Love and I had the wit to win:
We drew a circle that took him in!—Edwin Markham*

THIS ISSUE OF MINNESOTA MEDICINE is dedicated to one of the largest Medical Schools in the United States—The University of Minnesota Medical School of Minneapolis. Last fall, our enrollment increased to 227 first year students! Our alumni will recall the many men who made this school both large and excellent. The school contains some faces which are new to many of you—men who carry on their predecessors' traditions of greatness.

After 13 years as an Internist in a group practice in Brainerd, Minnesota, I returned to full time work in the Department of Family Practice Community Health at our University Medical School. The past four years have given me a chance to identify two misconceptions:

1. Some academicians seem to be convinced that practicing physicians are more concerned with business management than with quality medicine.
2. Some practicing physicians seem to believe that the academician is more concerned about research than patient care.

Neither of these thoughts is correct. The practicing physician and the academician are both con-

cerned about quality medicine and patient care; both have to work in busy clinics; both must keep abreast of the rapid advances in medicine, and both serve as teachers of patients and colleagues.

Those of us who work within the private sector of medicine and those who work within the University are all part of the same group. We have all graduated in the same basic discipline and share the common bond of a technical language.

To me, the most exciting discovery within the University has been finding a new group of colleagues . . . medical sociologists, anthropologists, and other behavioral scientists. These valuable and underpaid consultants have not always been welcomed into the medical community for they speak a different technical language. Despite our differences, they provide us with research tools which allow us to use solid scientific methodology for studying groups. Advances in biological sciences have required research with groups of living organisms and the laboratory scientists would make less progress if they had to work with single organisms. It is time for clinical medicine to extend our boundaries, work with groups of people, and advance *together* beyond the limits imposed by the study of single cases.

John B. O'Leary, M.D.*
Guest Editor

*Associate Professor, Department of Family Practice and Community Health, University of Minnesota, Minneapolis.

The Medical School Expands

THIS ISSUE OF MINNESOTA MEDICINE, guest edited by Dean N. L. Gault and Dr. John Leary, is dedicated to the University of Minnesota (Minneapolis) Medical School and the papers are by members of its staff.

It is evident from Garrard's statistics* that Minnesota is a great supplier of physicians for the other 49 states, but we don't do too badly with 7% of Minnesota trained physicians practicing in their home state, about the national average for the home product staying home. Dean Mulhausen† describes the precipitous increase of the student body from classes of 163 in 1969 to 239 today about a 70% increase. He describes the major construction in being and contemplated to accommodate these gigantic classes. It would be

comforting to know that the funding for all this that he describes as "expected to be obtained" was actually in the bank. This expansion, incidentally, offers an immediate opportunity for practicing physicians to take part in the instruction of medical students.

Our medical school is renowned throughout the world. Its impact is felt wherever physicians practice. Its graduates, though concentrated in the states, are also found in many countries. A good share of the fundamental knowledge that constitutes medicine today is the result of research reported from the Minnesota campus. MINNESOTA MEDICINE is privileged to publish the papers collected for this issue and the Board of Editors wishes to thank the authors and the guest editors for their collaboration.

The Chemotherapy of Infectious Diseases

THE PERSONAL REMINISCENCES of Wesley Spink, M.D. regarding the drama of the discovery, development and clinical usage of sulfanilamide, penicillin and other antibiotics* gives us an interesting account of these historic discoveries. Dr. Spink is justly proud of the early and important contributions which he and his medical fellows made in this field. It was our good fortune in Minnesota that several of our physicians were able to contribute much to the understanding of the clinical applications of these most useful drugs. Not the least of these were the historic trials of streptomycin in experimental and clinical tuberculosis.

For those interested in the history of the development of penicillin at Oxford University the 1970 paper by Heatley¹ gives much of the background as to how Florey, Chain and Abraham and their colleagues solved the technical problems of

producing and extracting penicillin. These problems had baffled Fleming, the microbiologist who discovered penicillin, and the skills of chemists were needed for their solution.

The most dramatic and original discoveries made by Dr. Spink and his colleagues were the consequence of their work with human brucellosis. Their demonstration in Mexico that severe, acute infections with *Brucella melitensis* would respond to modest doses of chlortetracycline has stood the test of time. Tetracyclines today remain the most effective and safe agents for human brucellosis.

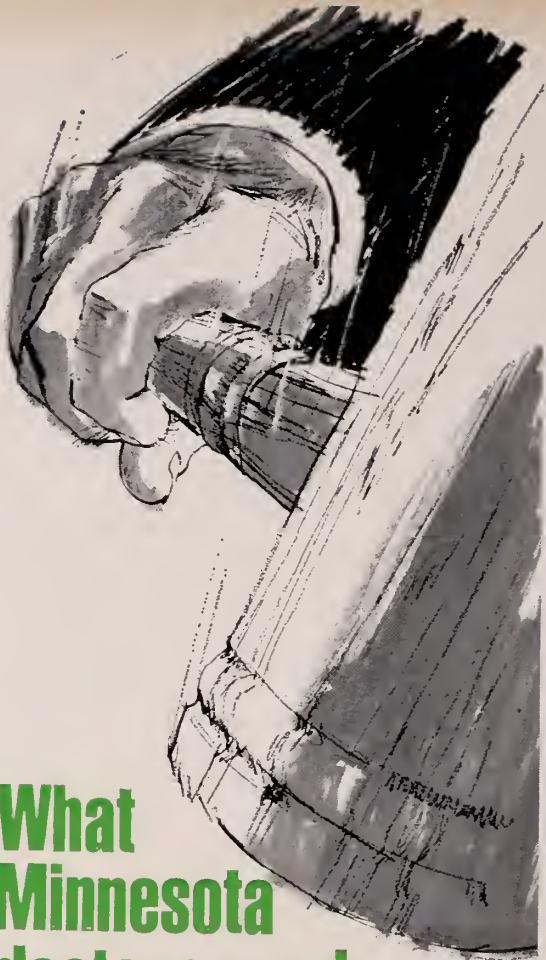

The convocation lecture by Dr. Spink, which is reprinted in this issue of MINNESOTA MEDICINE, marks the climax of his 36 years service to the University of Minnesota. We have appreciated the privilege of knowing this illustrious physician as teacher and friend.

Wendell H. Hall, M.D.

Medical School Facilities Planning and the Health Sciences Development Program

MEDICAL SCHOOL planning for facilities received major impetus in 1966 from a recommendation of a Citizen's Advisory Commission that the University of Minnesota Medical School increase the size of the entering class in the 1970's. This recommendation was based upon the Hill Family Foundation supported study, "Health Manpower for the Upper Midwest" which documented the shortage of physicians and other health care personnel in the State and region. In response to this recommendation and the need for more physician manpower, the Medical School entering class size was increased to 227 in 1970 and to 239 in 1973 from a base of 163 in 1969.

In 1970 the Medical School initiated a new curriculum which stressed interdisciplinary instruction, an accent on outpatient teaching, and the concept of lifelong, self-learning by the student. In addition, the reorganization of the University's various health related schools into the Health Sciences Center underscored the important interrelationships of Health Sciences personnel in the delivery of health care.

Based upon these needs to accommodate increased numbers of health sciences students, to

develop a new curriculum, and to foster interdisciplinary health sciences instruction, facilities planning culminated in the Health Sciences Development Program. This program consists of a combined Dental, Medical and Public Health facility to be built in two phases, a building for the School of Pharmacy, a materials receiving area, and a new parking ramp for patients and staff. Particular attention was given to planning of internal and external traffic patterns, site development in a densely populated area, parking needs and flexibility of design of the buildings.

In 1970-71 construction of the first of the new facilities, Unit A, a 19 story structure, was begun. Planned to be completely finished in January, 1974, classroom facilities devoted to basic sciences instruction of students will be ready in September, 1973, for the 1973-74 school year. To be completed at a cost of \$46 million, funds have been obtained from State and Federal sources. Unit A consists mainly of Dental School space and also includes basic sciences teaching laboratories, classrooms, auditoria, and Medical and Public Health School departmental areas.

Construction of the major Medical School fa-

Figure—Model of the Health Sciences Development Program viewed from the northwest. Unit A, the tallest structure, is in the middle of the picture. Unit B/C is to the right, or south of Unit A. Unit F is to the left, or northeast of Unit A. The current Health Sciences buildings are in the right foreground.

Now there's an ethical, personalized program for conditioned response therapy for **ENURESIS**. With greater public awareness of the problem of enuresis and its control, many treatment programs have become available. But, most of them ignore the vital role of the physician in examining the child and counseling with both the child and parent to achieve success.

Now, Dynamed Inc. is pleased to introduce the *Companion* Conditioned Response Therapy Program that includes examination and counseling as an integral part of the treatment. And even after the parent has expressed an interest in the *Companion* program no salesman will call.

Companion personalizes the control program with the help of miniaturized circuitry. It's no longer necessary to awaken the entire household with a noisy bell used in many programs. *Companion* utilizes a thin circuit moisture sensor in the crotch area of the bedclothes. There is also a tiny battery operated oscillator signal at the child's ear. Placement of the sensor means the signal goes off the instant urine is released, not after it is absorbed by bedclothes and sheet. The personalized signal at the child's ear aids in development of individual responsibility in the child being treated.

If you're interested in a packet of helpful information about enuresis and the *Companion* program, send the attached coupon or call Dynamed.

NAME _____

ADDRESS _____

CITY _____ STATE _____ ZIP _____

city, Unit B/C, is scheduled to begin in 1974. Estimated cost is \$33 million. This facility will be attached to and will functionally interrelate with Unit A. Unit B/C consists of an outpatient clinic, classrooms and auditorium, a learning resources center, a small amount of Medical School departmental space and an unfinished, shell area which will be completed in the future. Funding for the unit is expected to be obtained from State Legislative sources, Federal programs, and private donations. The completed unit will greatly relieve the acute space shortage of the school and will markedly enhance the curriculum for medical students. Until the completion of Unit B/C, the Medical School will depend upon development of off campus surge space and temporary space adjustments in order to accommodate the large classes already receiving instruction at the school.

Units A and B/C are located directly across Union Street from Millard Hall and the Mayo Building and extend from Washington Avenue to the Diehl Hall Biomedical Library.

In spring, 1973, construction of a new parking ramp, accommodating 2000 automobiles, will begin. The location of this ramp at the periphery of the Health Sciences campus will allow easy access from major traffic arterials supplying the campus and will decrease automobile congestion within the campus. Special buses, traversing the short distance to the new buildings and the Mayo Complex,

will be a feature of the parking ramp.

Unit E, a supply and receiving area serving the Health Sciences buildings, has been started on River Road, next to the Variety Club Heart Hospital. Unit K, the Cardiovascular Research Unit, is being constructed atop Unit E. Supported entirely by private donations, Unit K will provide facilities for research into cardiovascular and related disorders.

Unit F, the School of Pharmacy facility, is planned for construction on Washington Avenue, just north of the newly constructed Unit A.

Planning for the needs of the Medical School and the Health Sciences remains an ongoing activity. The need to replace obsolete clinical facilities and to develop space for new educational and research programs of the Medical School continues to receive faculty, staff and student attention.

Developed physical facilities are a significant portion of the many and varied resources needed by the School to effectively pursue its programs in medical education. The understanding and support of the public and the encouragement of the practicing community of physicians continue to be vital to the provision of these resources so important to the education of physicians and the expansion of medical knowledge.

Robert O. Mulhausen, M.D.
Assistant Dean, Medical School
Associate Professor of Medicine

Squamous Cell Carcinoma of the Head and Neck

DURING THE LATE 1950's and early 1960's the concept of combined therapy for cancer of the head and neck was suggested. Preoperative irradiation therapy followed by excisional surgery was used in an attempt to increase survival in patients who had tumors not successfully treated by either surgery or irradiation alone.¹

To the patient, combined therapy means four to six weeks of external irradiation, a rest period of four to six weeks, and then definitive radical excisional surgery. The cost of this approach in terms of the patient's time, well-being, and money is significant and can be justified only by a meaningful increase in survival. To date, only Goldman and co-workers² carefully controlled prospective analysis and uncompromising protocol applied to advanced laryngopharyngeal cancers (stages II, III, and IV, American Joint Committee

for Cancer Staging) has demonstrated a significant increase in survival rates. The decision on the use of combined therapy in treating other cancers of the head and neck awaits other controlled studies to provide the needed guidelines.

Duvall, Adams, Pollack, and Charyula's report* of 584 patients promises to provide some insight into the value of combined therapy but leaves the reader disappointed. Of their 584 patients, only 69 were treated in a combined protocol and just 21 were available for determinate analysis at five years. These 21 cases represent four different tumor problems (cancer of the larynx, base of tongue, pyriform sinus, and tonsil). The 69 patients represent five distinct tumor problems (cancer of larynx, base of tongue, oropharynx, pyriform sinus, and paranasal sinuses). Not even preliminary conclusions are justified by analysis of 21 patients with four diseases or 69 patients with

*See page 480.

five diseases. Remaining unanswered are the important questions: Does preoperative irradiation actually alter survival rates and decrease local recurrences and what is the optimal dosage of irradiation?

Cancer of the base of the tongue has long been considered a unique problem in head and neck oncology. Hayes Martin considered these growths inoperable in the 1940's because of their relatively inaccessible location and because he believed that these tumors were more anaplastic and more widely metastasizing than other tumors of the upper aerodigestive system. Results of radiation therapy were disappointing. Between 1952 and 1962, 87% of the patients with cancer of the tongue base at the Memorial Hospital for Cancer and Allied Diseases³ were treated surgically. The same change in approach has occurred at the Mayo Clinic. Between 1960 and 1967, 147 patients with cancer of the tongue base were evaluated. Of these, 102 underwent operation as their primary treatment, 27 had irradiation therapy, 13 were inoperable and five could not undergo operation because of medical contraindications; four had surgical treatment after 1967 for recurrence after radiation therapy. The overall survival for those treated surgically was 42%.⁴ There is no statistical evidence to support the concept that these tumors

are biologically different from other oral and pharyngeal cancers or that they are uniquely lethal. Rather, the tongue base is a silent area and the tumors are diagnosed later than more accessible cancers. I think that surgery is the treatment of choice for cancer of the tongue base, and combined therapy may improve overall results.

Prospective protocols are necessary as investigative tools to establish validity of concepts, but they are not prescriptions for therapy. It would be ideal if the protocols proposed by Duvall et al. could be directly applied to the realities of treating patients with tumors of the head and neck. All that would be needed then would be clinical staging and a tissue diagnosis. Unfortunately, cancer occurs in individuals, and individualization of therapy requires judgment and informed consent from the patient. For example a T₁ vocal cord cancer occurring in an elderly woodsman who will be lost to regular follow-up might well be treated one way and the same growth in a middle-aged urban attorney in another without compromising the potential well-being of either.

Individualization of therapy for a given patient with a specific tumor remains fundamental to the treatment of patients with squamous cancer of the head and neck.

Gilles de la Tourette's Syndrome

THERE ARE few disorders that have produced a more striking visual and auditory impact on this observer than Gilles de la Tourette's syndrome. Over the past two decades I have seen three individuals with the syndrome, two preadolescent boys and a girl in her twenties in whom the onset of the disorder was in her prepubertal years.

Developmental milestones are usually reached normally. Initial signs, in most cases appearing between the ages of three to 12 years, consist of frequent inappropriate blinking, less often facial, arm, or shoulder tics or head bobbing. Within a few years, the tics progress from the face to the proximal limb muscles and "vocal tics" become prominent. These take the form initially of grunts, coughs or barks. After several years, forced echolalia (involuntary repetition of words uttered by others) become evident along with hisses, coughs, or spitting.

Electroencephalographic changes have been common in most series but the findings have been neither specific nor characteristic. Minor motor asymmetries and a greater than expected frequency of left-handedness have been noted by Sweet, et al.* who have personally studied 20 patients. The significance of these findings is not known.

The concise survey of 485 cases Abuzzahm and Anderson† nicely summarizes the findings of this disorder which has eluded pathophysiologic explanation. The good response experienced with haloperidol which blocks dopamine receptors suggests, but does not prove, that dopamine excess underlies the syndrome and that this disorder is one of altered neurotransmission.

Decubitus Ulcers Yield to

Travase[®] Ointment

brand of **Sutilains**

Before treatment, necrotic matter coated the inner surfaces of this decubitus ulcer.

After six days of TRAVASE therapy, debridement is nearly complete and granulation evident.

Therapy—Observe Its Effects in 48 hours
The recommended nursing technique is without deviation, this procedure can show visible improvement within 48 hours of treatment. If no dissolution of slough occurs by then, application is unlikely to be rewarding. A break in procedure, usually due to use of drying or antiseptic agents which impair the effectiveness of the enzyme in TRAVASE).

Travase® Ointment brand of Sutilains

APPLICATION TECHNIQUE: TRAVASE Ointment is indicated as an adjunct to established methods of wound care for biochemical debridement. It dissolves and facilitates the removal of necrotic tissues and purulent exudates.

TRAVASE enzymes are selective. Virtually inactive on viable tissue.

When this recommended nursing technique is followed without deviation, this procedure can generate visible improvement within 48 hours . . .

(Ulcer being irrigated) Thoroughly cleanse and irrigate the wound area using only sterile water or sodium chloride solution. Be sure to cleanse the wound of any antiseptics or heavy-metal antibacterial agents which may interfere with the enzyme activity.

Thoroughly soak the wound area. Where practical, tubbing or showering is suitable. Or wet soaks with gauze pads may be used. Remember to avoid chemical cleansing agents which may interfere with the therapy.

With a sterile cotton swab or finger cot, apply a very thin layer of TRAVASE Ointment. The ointment spreads easily and only a small amount is needed (a small dab of ointment will cover an area as big as the back of a hand).

Be sure, though, to rub the ointment well into every crack or crevice of the wound and overlap the surrounding skin one-fourth to one-half inch beyond the area to be debrided—to be sure of complete coverage.

Apply loose, wet dressings, thoroughly soaked in sodium chloride solution or sterile water to the area to be debrided only.

Cover the moist dressings with an occlusive wrap (Saran wrap, Telfa Pads, or other plastic wrappings) to keep wound site moist. Do not extend occlusive wrap over 1/2 inch beyond area to be debrided.

When changing dressing, gently wipe away the dissolved material. Repeat the complete dressing procedure, including application of TRAVASE Ointment, four times daily.

The ulcer shown in these photos is simulated on a model in order to demonstrate the correct TRAVASE application technique.

_____ Additional Information on TRAVASE® Ointment (brand of Sutilains)

_____ In-service training program

_____ Comment _____

DESCRIPTION: TRAVASE® (brand of sutilains) Ointment is preparation of proteolytic enzymes, elaborated by *Bacillus subtilis* hydrophobic ointment base consisting of 95% white petrolatum polyethylene. One gram of ointment contains approximately units* of proteolytic activity.

ACTION: TRAVASE Ointment selectively digests necrotic so proteolytic action. It dissolves and facilitates the removal of tissues and purulent exudates that otherwise impair formative granulation tissue and delay wound healing (4).

At body temperatures these proteolytic enzymes have optimum pH range from 6.0 to 6.8.

INDICATIONS: For wound debridement (1,2)—TRAVASE Ointment is indicated as an adjunct to established methods of wound care biochemical debridement of the following lesions:

- Second and third degree burns,
- Decubitus ulcers,
- Incisional, traumatic, and pyogenic wounds,
- Ulcers secondary to peripheral vascular disease.

CONTRAINDICATIONS: Application of TRAVASE (brand of sutilains) Ointment is contraindicated in the following conditions:

- Wounds communicating with major body cavities,
- Wounds containing exposed major nerves or nervous tissue,
- Fungating neoplastic ulcers,
- Wounds in women of child-bearing potential—because of laboratory evidence of effects of TRAVASE upon the fetus.

WARNING: Do not permit TRAVASE Ointment to come into contact with the eyes. In treatment of burns or lesions about the head or neck, the ointment inadvertently come into contact with the eyes, be immediately rinsed with copious amounts of water, preclude further contact.

PRECAUTIONS: A moist environment is essential to optimal enzyme activity. Enzyme activity may also be impaired by certain antiseptics and detergents (benzalkonium chloride, hexachlorophene, iodine, and nitrofurazone) may render the ointment ineffective to the action of the enzyme (3). Compounds such as containing metallic ions interfere directly with enzyme activity, whereas neomycin, sulfamylon-streptomycin, do not affect enzyme activity. In cases where adjunctive topical antibiotics have been used and no dissolution of slough occurs after the TRAVASE Ointment for 24 to 48 hours, further application, but interference by the adjunctive agents, is unlikely to be reversed.

In cases where there is existent or threatening invasive infection appropriate systemic antibiotic therapy should be instituted.

Although there have been no reports of systemic allergic reactions in humans, studies have shown that there may be an antibody response to absorbed enzyme material.

ADVERSE REACTIONS: Adverse reactions consist of mild, transient, paresthesias, bleeding and transient dermatitis. Pain usually controlled by administration of mild analgesics. Side effects enough to warrant discontinuation of therapy occasionally have been reported.

If bleeding or dermatitis occurs as a result of the application (brand of sutilains) Ointment, therapy should be discontinued. Toxicity has been observed as a result of the topical application of TRAVASE Ointment.

Dosage and Administration

STRICT ADHERENCE TO THE FOLLOWING IS REQUIRED FOR OPTIMUM RESULTS OF TREATMENT

1. Thoroughly Cleanse and Irrigate Wound Area with sterile water or water solutions. Wound **MUST** be cleansed of any heavy-metal antibacterials which may denature enzyme substrate characteristics (e.g., Hexachlorophene, Silver Nitrate, Benzalkonium Chloride, Nitrofurazone, etc.).
2. Thoroughly moisten wound area either through tubbing or wet soaks (e.g., sodium chloride or water solution).
3. Apply TRAVASE Ointment in a thin layer assuring it covers all necrotic tissue and complete wound coverage 1/4 to 1/2 inch beyond the area to be debrided.
4. Apply loose wet dressings.
5. Repeat entire procedure 3 to 4 times per day for best results.

How Supplied

3P3002 TRAVASE Ointment is supplied sterile in one-half ounce (14.2 g.) containing 82,000 casein units of sutilain in a hydrophobic ointment base.

The ointment must be stored under refrigeration at 2° to 10° (35° to 50° F).

Introduction of the Department Heads of the University of Minnesota Medical School

A MEDICAL SCHOOL is an organization of persons; these persons are commonly categorized in groups: faculty, students, and technical, administrative, and clerical personnel. The excellence of the medical school depends on the collective quality and performance of these persons. The University of Minnesota Medical School has been fortunate throughout its history to have attracted men and women who have advanced and sustained the School's fame as a leading academic medical center of the United States and the world. Not only has the School been the major source of the health manpower for the State of Minnesota, but it has contributed notably to the advances in biomedical sciences and health care for all mankind.

In the Medical School's organization one group has through the years been responsible for distinguished leadership of the School's programs. This group is the Heads of Departments. These scientists assume the responsibility for guiding the activities of their departments in concert with the School's objectives; they have served to maximize the tremendous energies of the faculty and students.

It is with pride that I, as Dean, have this opportunity to present to the readers of MINNESOTA MEDICINE, the Heads of the Departments of the University of Minnesota Medical School in the year 1973:

N. L. Gault, Jr., M.D., Dean
Guest Editor

John A. Anderson
Professor and Head
Department of Pediatrics 1954-
University of Minnesota BS '30, MB '33, MD '34, PhD '40.
Previous University appointments:
Stanford University 1949-54
University of Utah 1943-49
University of Minnesota 1937-43

Wallace D. Armstrong
Professor and Head
Department of Biochemistry 1946-
University of Texas BA '26, New York University MS '28,
University of Minnesota PhD '32, MD '37.

UNIVERSITY OF MINNESOTA—MINNEAPOLIS

A. B. Baker
Professor and Head
Department of Neurology 1969-
Director of the Division 1946-69
University of Minnesota BA '28, BS '29, MB '30, MD '31,
PhD '34.

Ellis S. Benson
Professor and Head
Department of Laboratory Medicine and Pathology 1972-
Head, Department of Laboratory Medicine 1966-72
Augustana College AB '41, University of Minnesota MD '45.

Shelley N. Chou
Professor and Acting Head
Department of Neurosurgery 1970-
St. John's University, Shanghai, China BS '48, University of Utah
MD '49, University of Minnesota MS '54, PhD '64.

Edward W. Ciriacy
Professor and Head
Department of Family Practice and Community Health 1973-
Pennsylvania State College BS '48, Temple University MD '52.

DEPARTMENT HEADS

Richard V. Ebert
Professor and Head
Department of Medicine 1966-
University of Chicago BS '33, MD '37.
Previous University appointments:
University of Arkansas 1954-66,
Northwestern University 1953-54,
University of Minnesota 1946-53

Eugene Gedgaudas
Professor and Head
Department of Radiology 1969-
University of Munich, Germany, MD '48.
Previous University appointment:
University of Manitoba, Canada 1957-1963

Eugene D. Grim
Professor and Head
Department of Physiology 1968-
Kansas State College BS '45, MS '46, University of Minnesota
PhD '50.

Robert W. Goltz
Professor and Head
Department of Dermatology 1971-
University of Minnesota BS '43, MB '44, MD '45.
Previous University appointments:
University of Colorado 1965-71
University of Minnesota 1950-65

UNIVERSITY OF MINNESOTA—MINNEAPOLIS

John E. Harris
Professor and Head
Department of Ophthalmology 1958-
University of Toledo BS '35, State University of Iowa MS '38,
PhD '40, University of Oregon MD '50.
Previous University appointments:
University of Oregon 1951-58
University of Pennsylvania 1941-42
State University of Iowa 1940-41

William Hausman
Professor and Head
Department of Psychiatry 1969-
Washington University MD '47
Previous University appointments:
Johns Hopkins University 1966-69

Frederic J. Kottke
Professor and Head
Department of Physical Medicine and Rehabilitation 1952-
University of Minnesota BS '39, MS '41, PhD '44, MD '45.

Arnold Lazarow
Professor and Head
Department of Anatomy 1954-
University of Chicago, BS '37, MD '41, PhD '41
Previous University appointments:
Western Reserve University 1943-54

DEPARTMENT HEADS

Seymour H. Levitt
Professor and Head
Department of Therapeutic Radiology 1970-
University of Colorado BA '50, MD '54.

Previous University appointments:

Medical College of Virginia 1966-70

University of Oklahoma 1963-66

University of Rochester 1962-63

University of Michigan 1961-62

John H. Moe
Professor and Head
Department of Orthopedic Surgery 1969-
Director of the Division 1957-69
University of North Dakota BS '27, Northwestern University
MB '29, MD '30.

John S. Najarian
Professor and Head
Department of Surgery 1967-
University of California, Berkeley AB '48, MD '52.
Previous University appointments:
University of California, Berkeley 1963-67.

Michael M. Paparella
Professor and Head
Department of Otolaryngology 1967-
University of Michigan BS '53, MD '57.
Previous University appointments:
Ohio State University 1964-67
Harvard Medical School 1963-64

John J. Sciarra
Professor and Head
Department of Obstetrics and Gynecology 1968-
Yale University BS '53, Columbia University MD '57.
Previous University appointments:
Columbia University 1960-68

Frederick E. Shideman
Professor and Head
Department of Pharmacology 1962-
Albion College BA '36, University of Wisconsin PhD '41,
University of Michigan MD '46.
Previous University appointments:
University of Wisconsin 1952-62
University of Michigan 1942-52
University of Wisconsin 1936-42

Frederick H. Van Bergen
Professor and Head
Department of Anesthesiology 1957-
Director of the Division 1954-57
University of Minnesota BS, MB '41, MD '42, MS '52.

Dennis W. Watson
Professor and Head
Department of Microbiology 1964-
University of Toronto BSA '34, Dalhousie University MSC '37,
University of Wisconsin PhD '41.
Previous University appointments:
University of Wisconsin 1941-49.

A Decade of Neurosurgery

SHELLEY N. CHOU, M.D., Ph.D.*

IN THE PAST DECADE significant progress has been made in the field of neurosurgery along a broad front ranging from methods of diagnosis to specific surgical therapy. This has been made possible, in part, because of progress made in allied disciplines such as neurology, neuroradiology, neuroanesthesiology and neuropharmacology. There have been valuable advances achieved in neurosurgical diagnostic techniques and procedures. One such useful procedure is brain scan. This is atraumatic to the patient and does not disturb cerebrospinal fluid circulation or cerebral hemodynamics. A positive or a negative scan can be equally meaningful in ruling in or ruling out certain types of intracranial pathology because of known uptake patterns of these lesions. Neuro-radiologic procedures such as angiography and pneumoencephalography have been refined to the point where a diagnosis of the presence and the location of the lesion can be extremely accurate. More precise localization is possible not only because of our new knowledge in anatomy of minute parts of the brain but also due to increasing capabilities to demonstrate radiologically minor variations of intracerebral structures. [One could even frequently make a reasonably good estimate as to the histology of such a lesion based upon certain features of the contrast study.] Angiographic studies can now be done with selective injection of specific vessels desired. Films can be obtained in different projections. There can be magnifications of the projections and there are additionally available subtraction techniques so as to better visualize the vascular pattern in the lesion by eliminating the skull shadow on the film by virtue of special electronic techniques. Angiographic studies of spinal cord vascular lesions such as arteriovenous malformation are also possible by cannulating selective intercostal vessels via the femoral route, although the procedure is more time consuming and the yield less fruitful.

In the area of pneumoencephalographic studies the use of a special chair and of tomographic exposure of the brain has made it possible to localize a lesion extremely accurately.

For non-tumorous pathological conditions such as hydrocephalus and cerebrospinal fluid fistulae the use of an isotope tracer study for cerebrospinal fluid circulation and/or cerebrospinal fluid leak is extremely valuable.

The control of increased intracranial pressure used to be the most difficult problem in neurosurgery. Now the use of steroids, pre, intra or postoperatively has contributed significantly to the successful control of intracranial pressure. More dramatically, hyperosmolar dehydrating agents such as Mannitol, which can be infused over a short period of time to reduce the intracranial pressure are also available. Its use, however, is usually for acute situations or to facilitate exposure at surgery.

The development and use of the microscope in neurosurgery has facilitated the surgical management of arteriovenous malformations, intracranial aneurysms, vascular tumors or other tumors in specific locations such as the cerebello-pontine angle and the parasellar region as well as peripheral nerve repair. The use of the microscope along with the development of the bipolar coagulation unit has made it possible to remove extensive spinal cord arteriovenous malformations.

Additionally, the availability of special vascular clips and the use of chemical reinforcing agents have made it possible to treat, frequently successfully, intracranial aneurysms located virtually in all conceivable locations. Still lacking are agents to combat cerebrovascular spasm associated with the rupture of cerebral aneurysms, although certain biochemical factors causing such spasm have been identified. If such spasms can be successfully controlled the mortality and morbidity rate associated with intracranial aneurysmal surgery should be negligible.

New techniques of controlling pain are being developed. Peripheral nerve or spinal cord stimu-

*Department of Neurosurgery, University of Minnesota Medical School, Minneapolis, Minnesota.

lation techniques have been developed over the past few years; though the exact neurophysiological basis for such techniques is still not known, it is possible that their effects are at the spinal cord level in controlling the gate of sensory input or at the brain stem or even at the cortical level. There is no question, however, that it does work in certain patients for pain relief. The use of dorsal column or peripheral nerve stimulation is still in its embryonic stage and in the next decade criteria in terms of selection of patients as well as development of more sophisticated instrumentation will undoubtedly make neurosurgical pain-relieving procedures very effective.

In the area of anesthesia, temporary induced hypotension can be extremely useful in certain operative procedures. The application of a clip on the aneurysmal neck, for example, would be one such situation, because hypotension renders the aneurysm less turgid and it is thus less likely ruptured with clipping. Generally hypotension does not have to be very long to achieve its purpose. The use of hypothermia can be very useful in certain neurosurgical operative procedures where temporary occlusion of one or more cerebral vessels is contemplated. Usually a moderate hypothermia of 27 to 26° C is adequate. With additional pharmacological control cardiac arrhythmia at this level of body temperature does not generally occur.

Pediatric neurosurgical management of birth

defects and hydrocephalus by various shunt procedures has made steady progress. The concept of team approach to care for these children with physiatrists, orthopedists and urologists is now well accepted.

Stereotactic neurosurgery has had its waxes and wanes partly due to periodic use of effective drugs (e.g. L-Dopa) to control certain movement disorders. However, it is still a form of effective treatment in selected patients of behavior disorders, movement abnormality, pain and seizure control.

In areas of trauma such as head injury and spinal cord injury progress made has been painfully slow. This is, in part, due to the fact that the fast moving vehicular type of injury often causes irreparable damage to the nervous system so that by comparison the progress which has been made in the neurosurgical management of trauma seems inadequate.

In looking ahead to the next decade it would seem that progress will continue to be made in the areas of pain control, peripheral nerve repair and in the availability of more sophisticated techniques at surgery to facilitate exposure and hemostasis. Research of possible applications of immunotherapeutic measures in management of tumors of the central nervous systems is on the horizon. Needless to say, there will be an extremely interesting and challenging decade ahead in neurosurgery.

Grow old along with me!

The best is yet to be,

The last of life, for which the first was made:

Our times are in His hand

Who saith "A whole I planned,

Youth shows but half; trust God: see all nor be afraid!"*

a major problem

2 out of 3
nosocomial infections
are gram-negative

Gram-negative bacteria magnified 10,000 times—color-tinted

Commonly encountered pathogens on all hospital services

Total pathogens 21,972
Source: Gosselin Audit of Pathology Cultures—1971

*GARAMYCIN Injectable is effective against susceptible strains of the pathogens indicated.

Highly appropriate spectrum for today's problem pathogens

GARAMYCIN Injectable offers a high degree of effectiveness against susceptible members of seven out of seven major gram-negative pathogens. These are:

Escherichia coli
Proteus, indole-negative
Proteus, indole-positive
Pseudomonas aeruginosa
Klebsiella
Enterobacter } species
Serratia

GARAMYCIN Injectable has also been shown effective in serious staphylococcal infections. It may be considered in those infections where penicillins or other less potentially toxic drugs are contraindicated and bacterial sensitivity testing and clinical judgment support its use.

Start with Garamycin

■ Broad gram-negative spectrum

Because of its broad gram-negative spectrum and its well-established clinical efficacy, GARAMYCIN Injectable can be considered for initial therapy in suspected as well as documented gram-negative sepsis.

Stay with Garamycin

■ Susceptibility of causative organisms confirmed

The results of susceptibility tests will, in most cases, demonstrate the causative organisms' sensitivity to GARAMYCIN Injectable. However, the decision to continue therapy with this drug should also be based on the severity of the infection and the important additional concepts contained in the Warning Box.

■ Relatively low incidence of adverse reactions

Risk of toxic reactions is low in patients with normal renal function who do not receive GARAMYCIN Injectable at higher doses or for longer periods of time than recommended.

■ Bacterial resistance has not been a problem

In the laboratory, resistance has been demonstrated to develop slowly in stepwise fashion. No one-step mutations to high resistance have been reported to date.

serious gram-negative infections (pneumonia, urinary tract infections, septicemia, and wound infections)*

On all in-patient services...

Garamycin[®]
 gentamicin sulfate injectable
I.M./I.V.

40 mg. per cc.

Each cc. contains gentamicin sulfate equivalent to 40 mg. gentamicin

WARNING

Patients treated with GARAMYCIN Injectable should be under close clinical observation because of the potential toxicity associated with the use of this drug. Ototoxicity, both vestibular and auditory, can occur in patients, primarily those with pre-existing renal impairment, treated with GARAMYCIN Injectable, usually during longer periods or with higher doses than recommended.

GARAMYCIN Injectable is potentially nephrotoxic, and this should be kept in mind when it is used in patients with pre-existing renal impairment. Monitoring of renal and eighth nerve function is recommended during therapy of patients with known impairment of renal function. This testing is also recommended in patients with normal renal function at the end of therapy who develop evidence of nitrogen retention (increasing BUN, NPN, creatinine or oliguria). Evidence of ototoxicity requires dosage adjustments

or discontinuance of the drug.

In event of overdose or toxic reactions, peritoneal dialysis or hemodialysis will aid in removal of gentamicin from the blood.

Serum concentrations should be monitored when feasible and prolonged concentrations above 12 mcg./ml. should be avoided.

Concurrent use of other neurotoxic and/or nephrotoxic drugs, particularly streptomycin, neomycin, kanamycin, cephaloridine, viomycin, polymyxin B, and polymyxin E (colistin), should be avoided.

The concurrent use of gentamicin with potent diuretics should be avoided, since certain diuretics by themselves may cause ototoxicity. In addition, when administered intravenously, diuretics may cause a rise in gentamicin serum level and potentiate neurotoxicity.

USAGE IN PREGNANCY Safety for use in pregnancy has not been established.

On all in-patient services...
in hospital-acquired gram-negative infections*

Garamycin[®]

gentamicin sulfate

Injectable

I.M./I.V.

40 mg. per cc.

Each cc. contains
gentamicin sulfate equivalent
to 40 mg. gentamicin

Also available:
GARAMYCIN[®] Pediatric Injectable, 10 mg. per cc.

GARAMYCIN[®] Injectable, brand of gentamicin sulfate U.S.P., injection, 40 mg./cc. Each cc. contains gentamicin sulfate equivalent to 40 mg. gentamicin
For Parenteral Administration

WARNING

Patients treated with GARAMYCIN Injectable should be under close clinical observation because of the potential toxicity associated with the use of this drug.

Ototoxicity, both vestibular and auditory, can occur in patients, primarily those with pre-existing renal damage, treated with GARAMYCIN Injectable, usually for longer periods or with higher doses than recommended.

GARAMYCIN Injectable is potentially nephrotoxic, and this should be kept in mind when it is used in patients with pre-existing renal impairment.

Monitoring of renal and eighth nerve function is recommended during therapy of patients with known impairment of renal function. This testing is also recommended in patients with normal renal function at onset of therapy who develop evidence of nitrogen retention (increasing BUN, NPN, creatinine or oliguria). Evidence of ototoxicity requires dosage adjustments or discontinuance of the drug.

In event of overdose or toxic reactions, peritoneal dialysis or hemodialysis will aid in removal of gentamicin from the blood.

Serum concentrations should be monitored when feasible and prolonged concentrations above 12 mcg./ml. should be avoided.

Concurrent use of other neurotoxic and/or nephrotoxic drugs, particularly streptomycin, neomycin, kanamycin, cephaloridine, viomycin, polymyxin B, and polymyxin E (colistin), should be avoided.

The concurrent use of gentamicin with potent diuretics should be avoided, since certain diuretics by themselves may cause ototoxicity. In addition, when administered intravenously, diuretics may cause a rise in gentamicin serum level and potentiate neurotoxicity.

USAGE IN PREGNANCY Safety for use in pregnancy has not been established.

INDICATIONS GARAMYCIN Injectable is indicated, with due regard for relative toxicity of antibiotics, in the treatment of serious infections caused by susceptible strains of the following microorganisms:

Pseudomonas aeruginosa, **Proteus** species (indole-positive and indole-negative), **Escherichia coli** and **Klebsiella-Enterobacter-Serratia** species.

Clinical studies have shown GARAMYCIN Injectable to be effective in septicemia and serious infections of the central nervous system (meningitis), urinary tract, respiratory tract, gastrointestinal tract, skin and soft tissue (including burns).

Bacteriologic tests to determine the causative organisms and their susceptibility to gentamicin should be performed.

Bacterial resistance to gentamicin develops slowly in stepwise fashion; there have been no one-step mutations to high resistance.

In suspected or documented gram-negative sepsis, GARAMYCIN may be considered as initial therapy. The decision to continue therapy with this drug should be based on the results of susceptibility tests, the severity of the infection, and the important additional concepts contained in the Warning Box. In the neonate with suspected sepsis or staphylococcal pneumonia, a penicillin type drug is usually indicated as concomitant antimicrobial therapy.

GARAMYCIN Injectable has been shown to be effective in serious staphylococcal infections. It may be considered in those infections when penicillins or other less potentially toxic drugs are contraindicated and bacterial susceptibility testing and clinical judgment indicate its use.

CONTRAINDICATIONS A history of hypersensitivity to gentamicin is a contraindication to its use.

WARNINGS See Warning Box.

PRECAUTIONS Neuromuscular blockade and respiratory paralysis have been reported in the cat receiving high doses (40 mg./kg.) of gentamicin. The possibility of these phenomena occurring in man should be considered if gentamicin is administered to patients receiving neuromuscular blocking agents such as succinylcholine and tubocurarine.

Treatment with gentamicin may result in overgrowth of nonsusceptible organisms. If this occurs, appropriate therapy is indicated.

ADVERSE REACTIONS

Nephrotoxicity: Adverse renal effects, as demonstrated by rising BUN, NPN, serum creatinine and oliguria, have been reported. They occur more frequently in patients with a history of renal impairment treated with larger than recommended dosage.

Neurotoxicity: Adverse effects on both vestibular and auditory branches of the eighth nerve have been reported in patients on high dosage and/or prolonged therapy. Symptoms include dizziness, vertigo, tinnitus, roaring in the ears and hearing loss. Numbness, skin tingling, muscle twitching, and convulsions have also been reported.

Note: The risk of toxic reactions is low in patients with normal renal function who do not receive GARAMYCIN Injectable at higher doses or for longer periods of time than recommended.

Other reported adverse reactions, possibly related to gentamicin, include increased serum transaminase (SGOT, SGPT), increased serum bilirubin, transient hepatomegaly, decreased serum calcium; splenomegaly, anemia, increased and decreased reticulocyte counts, granulocytopenia, thrombocytopenia, purpura; fever, rash, itching, urticaria, generalized burning, joint pain, laryngeal edema; nausea, vomiting, headache, increased salivation, lethargy and decreased appetite, weight loss, pulmonary fibrosis, hypotension and hypertension.

DOSE AND ADMINISTRATION

GARAMYCIN Injectable may be given intramuscularly or intravenously.

For Intramuscular Administration:

PATIENTS WITH NORMAL RENAL FUNCTION*

Adults: The recommended dosage for GARAMYCIN Injectable for patients with serious infections and normal renal function is 3 mg./kg./day, administered in three equal doses every 8 hours.

For patients weighing over 60 kg. (132 lb.), the usual dosage is 80 mg. (2 cc.) three times daily. For patients weighing 60 kg. (132 lb.) or less, the

usual dose is 60 mg. (1.5 cc.) three times daily.

In patients with life-threatening infections, doses up to 5 mg./kg./day may be administered three or four equal doses. This dosage should be reduced to 3 mg./kg./day as soon as clinically indicated.

*In children and infants, the newborn, and patients with impaired renal function, dosage must be adjusted in accordance with instructions set forth in the Package Insert.

For Intravenous Administration:

The intravenous administration of GARAMYCIN Injectable is recommended in those circumstances when the intramuscular route is not feasible (e.g. patients in shock, with hematologic disorders, or severe burns, or with reduced muscle mass).

For intravenous administration, in adults, a solution of GARAMYCIN Injectable may be diluted 100 or 200 cc. of sterile normal saline or in a sterile solution of dextrose 5% in water; in infants and children, the volume of diluent should be less. The concentration of gentamicin in solution, in both instances should normally not exceed 1 mg./cc. (0.1%). The solution is infused over a period of 1 to 2 hours.

The recommended dose for intravenous administration is identical to that recommended for intramuscular use.

GARAMYCIN Injectable should not be physically pre-mixed with other drugs, but should be administered separately in accordance with the recommended route of administration and dosage schedule.

HOW SUPPLIED GARAMYCIN Injectable, 40 mg. per cc., 2 cc. multiple-dose vials for parenteral administration.

Also available, GARAMYCIN Pediatric Injectable, 10 mg. per cc., 2 cc. multiple-dose vials for parenteral administration.

Projections of Future Need for Physicians in Minnesota*

H. MEAD CAVERT, M.D.†

DURING RECENT YEARS, citizens of Minnesota in the Upper Midwest, in concert with the entire United States, have insistently and increasingly posed numerous questions concerning the supply of effective physicians for meeting the health care needs of our communities now and in the near future. They are aware that, beginning with early years of planning in the mid-1960's, and bolstered through the Physician Augmentation Program in 1970 as well as increased legislative support, the Medical Schools of the state have responded vigorously with new or significantly enlarged entering classes of medical students. There are now 303 students in the first-year classes of 1972-73 at Duluth, Minneapolis, and Rochester. The important question remains for periodic review and adjusted projection of the number of physicians needed in the state and on in future years.⁸

In an extensive, well-documented study of June, 1965, sponsored by the Louis W. and Maud Hill Family Foundation, it was estimated that by 1975, Minnesota would be short from 200 to 300 physicians for the maintenance of the ratio of active physicians to population which existed in 1966.¹ On that basis, the Health Manpower Study Advisory Commission recommended that the University of Minnesota should expand its entering class to 400 students "at an early date and make plans for a further expansion to 250 at some time in the future."

To our knowledge, no similarly comprehensive study of the need for physician manpower in Minnesota has been conducted subsequently, although recently there have been major national studies and projections of future need for and supply of physicians.² These and any pertinent estimates of future needs for physicians must necessarily be developed from available, sound data bases, combined with certain assumptions involving qualitative judgment or even opinions, such as those

expressed in a future optimal or acceptable ratio of active physicians to population. The estimates and projections presented here have been derived from data selected in part on the basis of such judgments and viewpoints, albeit based on documented sources of information.

Current Status of Physician Supply in Minnesota

In its most recent annual report on distribution of physicians in the United States, the American Medical Association recorded a total number of 5863 physicians in Minnesota in 1971, or 151 per 100,000 population.³ Of that number, 5008 M.D.s were reported to be primarily involved in patient care, whether through office-based or hospital-based practice.

In Minnesota, any enumeration of active practicing physicians must take realistic account of the significant concentration of M.D.s at the University of Minnesota Health Sciences Center in Minneapolis and the Mayo Institutions in Rochester. Both centers employ large numbers of physician-faculty members engaged in teaching and research as well as patient care; both centers have large numbers of residents or medical fellows who are students and teachers as well as physicians involved in patient care; and finally, physicians at both institutions care for significant numbers of patients who are not citizens of Minnesota. For these reasons, in attempting to determine a realistic physician-population ratio for Minnesota, we estimate that the equivalent of 876 physicians should be subtracted from the reported number of active physicians in the state. Following this reduction, there remain 4132 M.D.s actively serving the population of Minnesota in 1971.

In 1971, Minnesota had a population of 3,877,000. There were 107 actively practicing M.D.s per 100,000 population in the state, after appropriate correction for the two large medical training centers. This ratio is only slightly greater than a similar index, 100 per 100,000, reported by the Northlands Regional Medical Program staff in

* Adapted from a report presented to the Education Division of the Appropriations Committee of the House, Minnesota State Legislature.
† Associate Dean.

their study of Minnesota's physician manpower in 1969.⁴ These physician-population ratios are substantially lower than the average comparable index reported for the entire United States. All of these figures, those for Minnesota as well as for the United States, attempt to report the current actual situation, and do not convey any connotation of an optimal or desirable value for the physician-population ratio.

Projection of Need for Physicians in 1985

We have attempted to estimate Minnesota's probable supply of and need for physicians in 1985. Nineteen eighty-five is a useful reference year for the future because authoritative regional population projections are available for that year, and because, by 1985, the full influence of the currently expanding medical student enrollment in Minnesota should be tangibly expressed in physician numbers and locations of practice in the state and region. By 1985 or before, most of the physicians who entered as medical students in 1975 or later will have become established in their locations of medical practice. In 1975, the University of Minnesota Medical School, Minneapolis will have approached its projected maximum plateau of total medical student enrollment. In 1976, the University of Minnesota, Duluth School of Medicine will enroll an entering class of 48 students. In the meantime, Mayo Medical School will have continued to advance its enrollment by annual addition of a first-year class of 40 students.

Based on reasonably conservative estimates of anticipated population growth, Minnesota will have a population of 4,522,000 in 1985.⁵ This figure, based upon a 19% increase in population from 1970 to 1985, has been reported recently by the Upper Midwest Council. The predicted number is quite consistent with current projections by the United States Bureau of the Census, utilizing conservative estimates of the future fertility rate in the United States, expressed as predicted family size.⁶

Using this population projection for 1985 and conservatively projecting the existing physician-population ratio to that year, we calculate that Minnesota's citizens will require the services of 4839 active physicians in 1985. Thus, to care for the future larger populations, there will be a need for 707 more medical doctors practicing in Minnesota in 1985 than in 1971.

In a study published in January, 1969, Dr. Winston Miller, Director of Northlands Regional

Medical Program, estimated an overall shortage of 993 medical doctors in Minnesota, 56% of that shortage pertaining to "personal physicians" that is, general physicians, internists and pediatricians.⁷ Dr. Miller excluded Olmsted County from his data to eliminate any distortion attributable to the location of the Mayo Clinic. If such a deficiency continues to exist in 1973, Minnesota will require an increment of 1700 practicing physicians by 1985 to meet the needs of population increase and to erase the estimated current deficit.

Projection of Physician Supply in 1985

The primary sources for future practicing physicians in Minnesota are the three medical schools in the state. Medical schools and graduate training programs from other states may serve as auxiliary sources of additional doctors for practice in this state, but over the years Minnesota has placed great reliance on and drawn heavily from graduates of its own medical institutions. We have projected the probable number of graduates from the medical schools in Minnesota to 1985 assuming a plateau at approximately 350 graduating M.D.s in 1980. We estimate that the total number of graduates produced by the three Minnesota schools will be slightly less than 4000 (4581) in the 15 years from 1971 through 1985.

To estimate the net gain in practicing physicians for Minnesota to be realized from that projected rate of M.D. production, it is necessary to make assumptions concerning several factors for which unfortunately, few or no "hard" data are available, especially in the prediction of future trends. We assume that:

1. On the average, 65 percent of M.D. graduates from Minnesota medical schools will establish practices in this state.
2. Annually, an average of 143 active physicians in Minnesota will retire, die, or otherwise become inactive; this factor assumes an average service span per active physician of slightly less than 30 years.
3. Any outflow of currently practicing M.D.s to other states will be balanced by an equal inflow of practicing physicians from elsewhere, thus maintaining on balance the 1971 base of active medical doctors in Minnesota.

On these assumptions, and after performing the indicated calculations on the projected number of M.D. graduates, 4581, we estimate that by 1985 the increased production by the medical schools will have *gained* on the current supply of active physicians in Minnesota by 833 additional M.D.s.

practicing (or nearly ready to practice) in the state.

In the meantime, the projected population increase in Minnesota will require by 1985 an additional number, 707 M.D.s, over the number active-practicing in 1971. Even acknowledging the considerable and rapid increase in the number of M.D.s graduating from the state's medical schools by 1985, that number, may be only slightly more than sufficient to offset the additional need for physicians created by the predicted population increase during the same period (833 vs. 707).

In 1969, Northlands Regional Medical Program estimated a shortage then existing in Minnesota communities of 993 practicing physicians. If we accept the assumptions and estimates presented above, significant progress toward reducing or eliminating that deficit by 1985 would have to result from alterations in factors other than currently anticipated production by Minnesota's medical schools during that period. Hopefully, we can expect a continuation of some net influx of medical school graduates from other states, especially those who may be attracted to Minnesota's graduate training centers for residency training programs. Until recently, nearly one-half of Minnesota's physicians have been graduates of non-Minnesota schools. Inflow of graduates from medical schools in other states could provide sufficient physicians (80) to reduce nearly to zero the projected deficit (-867) in Minnesota's physician manpower. The shortage of active physicians in 1985 would then be only 17 M.D.s $(-867 + 850 = -17)$.

Predictably, these estimates are sensitive to the several factors. The percentage figure selected for future retention rate of Minnesota M.D. graduates, for example, may be overly optimistic. The National Family Foundation study reported that, in recent decades, approximately 55% of medical graduates of the University of Minnesota established their practices in this state. Mindful of these data and tempering our optimism accordingly, we might reduce our assumption concerning future retention rate to a somewhat lower figure, say 60%. Other factors in the calculation remaining constant, we would then retain 2749 of medical graduates from Minnesota's medical schools in the fifteen year period, 1971-1985. On that premise, the net gain in practicing M.D.s for Minnesota would be 604, resulting in a *net deficit*, for population increase is accounted for, of 103 physicians. In that event, rather than

gaining slightly on a physician deficit reported to exist in 1969, Minnesota might fall even farther behind in its effort to overcome the state's doctor shortage. Presumably, to offset such a potential future deficit, Minnesota can continue to attract a significant inflow of additional new physicians graduated from medical schools in other states, a factor which in the past has made a substantial contribution to the medical manpower of this state.

Other Factors and Considerations

The preceding paragraphs illustrate that any attempt to extrapolate into the future the supply of and need for physicians in Minnesota necessarily involves several complications and speculations. In addition to the several factors previously discussed, there are numerous other influences, any combination of which may modify our view of physician need in 1985. Comments follow concerning some of these factors and influences.

The need for additional physicians would be accentuated by any or all of the several factors which increase the average demand by the public for medical and specifically physician services. Dr. Rashi Fein, Professor of the Economics of Medicine at Harvard Medical School and author of an authoritative monograph on the doctor shortage,⁹ has recently stated: "We can expect perhaps a 20% growth in demand for physicians' services between 1970 and 1980. This estimated increase in demand must be considered a lower limit, based on utilization at the present rate and at current prices."¹⁰ The increasing emphasis on education of the public in matters of health and disease, as well as mounting demand by many citizens for personal, individualized care may contribute to the demand predicted by Fein.

The working conditions and expectations of the present and coming generations of physicians may contribute additional influences. It seems probable that the average number of hours in the work week of physicians will decline, certainly not increase, in the next one to two decades.

The foregoing discussion has concentrated on "active" physicians in practice caring directly for patients. In the increasingly complex and extensive health care system in the United States of today and tomorrow, numerous additional M.D.s are required to perform a wide spectrum of duties requiring professional medical training and expertise, but not always involved directly in personal patient care. Examples which spring to mind include school health officers, public health officials, medical doctors serving insurance compa-

nies, and various administrative personnel. Surely Minnesota will wish to continue its outstanding record of contribution to these important functions. This factor too will increase effectively the number of physician graduates needed in Minnesota and the nation between now and 1985.

On the other side of the ledger, certain other factors or modifications in existing influences could reduce the projected need for medical doctors in Minnesota in 1985. Conceivably, various forms and combinations of existing and new allied health personnel may assume some of the time-consuming tasks now routinely performed by the physician, thus increasing his overall efficiency in patient care. But these additional auxiliary health workers will need to be trained in sufficient numbers and accepted by the patient public before their efforts can materially alter demand for physicians. Possibly improved mechanization, technology and communications will further improve the efficiency of practicing medical doctors in the future, but one can only speculate on the future impact of these modern supporting techniques.

In recent decades, the nation has relied for a significant portion of its physician manpower on foreign medical graduates who have established citizenship in this country. Minnesota's participation in this aspect of physician supply has been comparatively minor. Presumably the state does not wish to look to an increased influx of foreign medical graduates as a major contributor to Minnesota's future physician supply.

This discussion has not attempted to address the sensitive, difficult and complex issue of distribution of physician manpower and health services. Obviously modifications in distribution of doctors, either according to geographical location or professional specialty designation, or any combination of these, could strongly influence the total number of physicians needed at a future date as presented here. Distribution of either or both types undoubtedly affects perceptibly the important factor relating to retention of medical school graduates for location of their practices in the state. Various programs recently established or planned by the three medical schools should provide positive influences on distribution and retention of graduates.

Physician Manpower in the United States

Although this statement is focused primarily on the future need for and supply of medical doctors

in Minnesota, the situation in this state cannot be entirely isolated from national trends and projections of need for physician manpower. In 1971 the American Medical Association reported that there were in the United States 309,685 non-federal physicians to care for 204,280,000 people, 152 physicians per 100,000 population.³ Of this total number, 261,335 were recorded as actively involved in patient care, yielding a ratio of 261 active M.D.s per 100,000 persons. Another source estimates that there are 345,830 practicing physicians in the nation in 1973.¹¹

Debate continues among experts on the validity or inadequacy of the widespread use of the physician-population ratio as an index summarizing the status of physician manpower supply. Even less agreement exists concerning any particular value for an adequate, optimal or ideal physician-population ratio. Summarizing a discussion of this dilemma, a recent Carnegie Commission report by Blumberg commented: "None of the foregoing estimates appear to be well documented. Nevertheless, they provide rough guidelines to project needs for physicians per 100,000 population. Figures of 164 to 180 are indicated. These are for all active physicians in the United States."² These values for the ratio are considerably greater than those currently prevailing in the United States in most states, and in Minnesota.

Difference of opinion also continues among knowledgeable observers whether there is now a serious shortage in total numbers of physicians in the United States, or whether the problem is almost entirely a matter of inappropriate distribution of physician manpower. In 1970, the Carnegie Commission's report on "Higher Education and the Nation's Health" stated: "Although the debate over the extent of shortages of health manpower, critical shortages do exist."¹² More recently, a national news magazine, in an article on the physician shortage, reported data emanating from the National Institutes of Health which estimate the current shortage of practicing physicians to be 69,170 M.D.s.¹¹ The table of data proves, however, some note of encouragement that tangible progress has been made, inasmuch as the comparable shortage in 1965 was reported to be 238,131, indicating a 25% reduction in the deficit over an eight-year period.

Perhaps even more critical is the deficiency of adequate numbers of physicians for provision of high quality service in the primary care fields including general physicians, internists and pedi-

NEED FOR PHYSICIANS IN MINNESOTA

rians. Reviewing this aspect of the problem in 1972, a group of public health specialists from the University concluded: "The data available indicated the need for 133 physicians per 100,000 persons for primary care as against the available supply of about one-half as many."¹³ The authors suggest several possible approaches to at least a partial solution of this problem, such as decreasing physicians' non-patient care time and transferring some physician functions to other health care personnel.

Summary

A study in 1969 estimated a shortage of 993 physicians in Minnesota. The ratio of active physicians per 100,000 population, revised to account for the important influence of the two major health educational centers in the state, was 107 in 1971. Assuming a 19% population increase by 1985, Minnesota would require 707 additional physicians to maintain the existing physician-population ratio. Approximately 4581 new M.D.s should graduate from the three medical schools in Minnesota between 1971 and 1985. Assuming 65% overall retention of Minnesota M.D. graduates for location of practice in the state, and allowing for an average rate of retirement, death, and other inactivity of practicing physicians, we estimate a net gain of 133 additional active physicians in Minnesota, a number slightly more than sufficient to compensate for the anticipated population increase ($833 - 699 = +126$). The major portion of the current shortage would continue to exist, however, unless other compensating factors exerted a strong influence. Presumably the state can continue to expect a significant but quantitatively uncertain contribution to Minnesota's physician manpower by graduates from medical schools in other states. Until recently, nearly one-half of Minnesota's

TABLE

Estimated Need for Physicians in Minnesota, 1971-1985	
Shortage of physicians reported in 1969	993
Additional physicians needed to maintain existing ratio of 107 active physicians per 100,000 population, assuming a population increase of 645,000, 1971-1985	707
(4839-4132)	
Total additional physicians needed in 1985 (993+707)	1700

Estimated Supply of Physicians in Minnesota, 1971-1985	
Graduating M.D.s from three Minnesota medical schools, 1971-85 (projected plateau at 350 graduates annually after 1980)	4581
Graduating M.D.s establishing practice in Minnesota (assumes 65% retention; 4581×0.65)	2978
Deduction of physicians for replacement of retired, deceased or inactive M.D.s (143 annually \times 15 years)	2145

Balance of Supply vs. Need by 1985	
Net gain by 1985 of graduates practicing in Minnesota (2978-2145)	833
Remaining net gain of M.D.s after accounting for population increase (833-707)	(+)126
Remaining net deficit of physicians in 1985 (-993+126)	(-)867
Additional inflow of M.D. graduates from medical schools in other states; if 850 (or $\frac{1}{2}$ of total additional physicians needed)	uncertain Net (-) 17 near balance

physicians have been graduates of non-Minnesota schools, a percentage which now may be declining. Inflow of graduates from medical schools of other states could provide sufficient physicians (850) to reduce nearly to zero the projected deficit (-867) in Minnesota's physician manpower. The shortage of active physicians in 1985 would then be only 17 M.D.s ($-867 + 850 = -17$).

EDWARD CIRIACY, M.D.*

THE STATE OF Minnesota, we currently have a deficit of some 722 family physicians based upon minimum need of 56 family physicians per 100,000 population. The net loss of family physicians in the past two years has been 37 per year by reason of death, retirement, moving, etc. As we make plans for future health care, it is essential to look at the projected population growth within the State. This is projected to go from a total in 1970 of 3.8 million to 4.5 million in 1985. Projection of annual needs to replace the current losses and to meet the needs of increased population, result in the following:[†]

1. The projected increase in population 1973-1983 is 460,000 and will require an additional 257 physicians or an average of 25 per year.
2. Retirement of the current base deficit of 722 physicians over a ten year period of time will result in a need for 70 additional physicians per year.
3. Replacement of the annual attrition of physicians will require replacement at the rate of 30 per year.

This will result in a total figure of approxi-

mately 125 family physicians needed annually for the next ten years, probably a conservative figure inasmuch as all of the health planning areas show a considerably higher than normal percentage of the family physicians being over the age of 55. This averages 38.3% throughout the State and ranges anywhere from 26.6% in Planning Area B to 41.9% in Planning Area E (Figure 1). Normally, we would expect to have only 20% of these physicians over the age of 55.

The Department of Family Practice and Community Health at the University of Minnesota has as its primary objective the training of family physicians to meet this need. The development of such a program came as a result of a feasibility study done in 1966. The program was actually initiated in 1968; became a division of the Department of Internal Medicine in 1969 and subsequently a free-standing department in 1970. The current faculty consists of nine full time physicians of whom seven are family physicians, one an internist and one a psychiatrist. A full time psychologist, educational psychologist, clinic manager and faculty member specializing in the field of communications are part of our faculty. Another five full time physician faculty serve as

*Professor and Head, Department of Family Practice and Community Health.
[†]Statistical research by John McConnell, M.D. and Michael Chemel of the Department of Family Practice and Community Health, University of Minnesota.

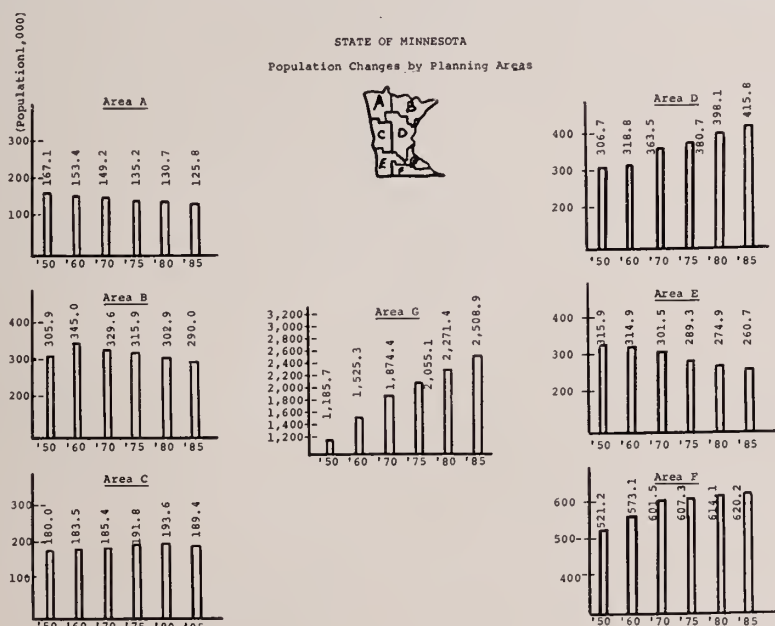

Figure 1

unit Program Directors at the various community affiliated hospitals and consists of faculty members in the fields of OB/GYN, family counseling, hospital administration, anthropology, and biostatistics.

Voluntary faculty with clinical departmental appointments number a total of 257 of whom 242 are family physicians, 12 are surgeons, two are internists, one a dermatologist, and one an osteopath. This latter group of clinical faculty support both the graduate and undergraduate education programs of the Department within the community.

Hennepin County General Hospital has five full time physicians; St. Paul Ramsey Hospital has three, all of whom are members of the departmental faculty. The two county hospital programs are academically related to the Department of

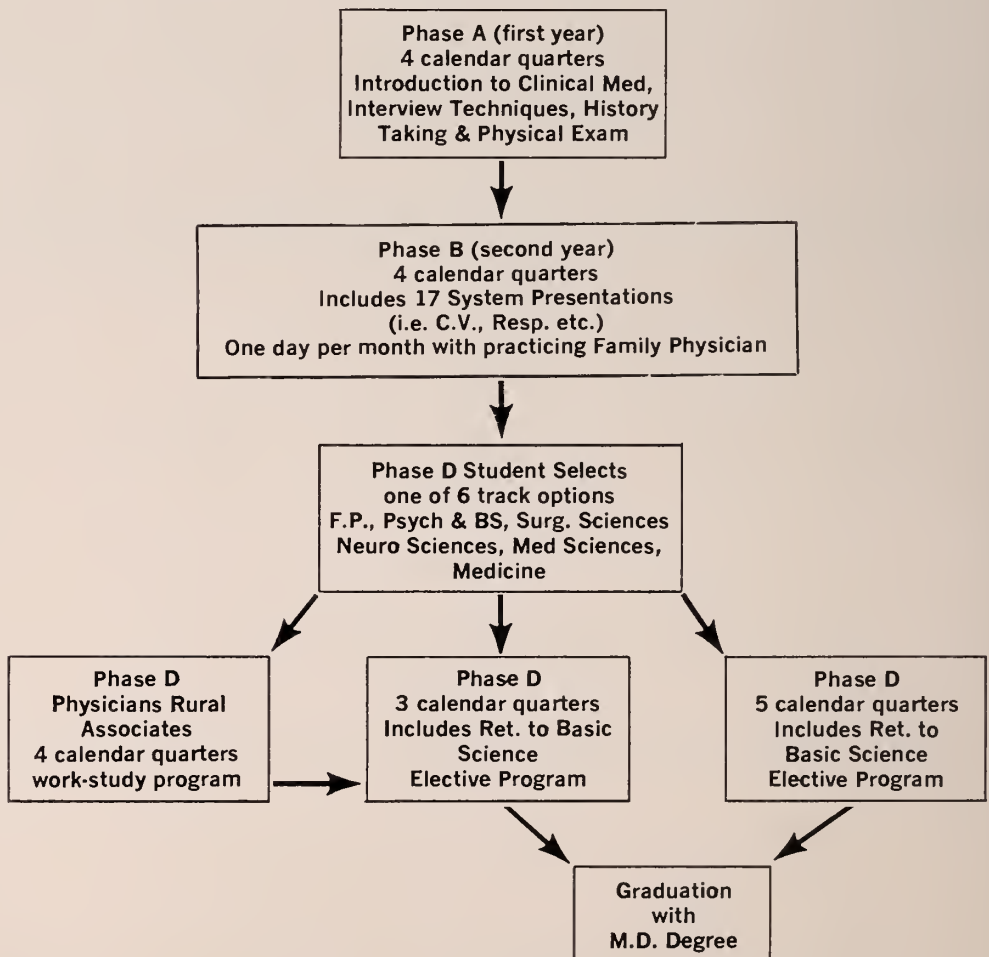

Family Practice and Community Health.

Undergraduate Activities

The Department of Family Practice and Community Health has undertaken multiple undergraduate responsibilities within the new curriculum structure. This structure is delineated in Table 1.

The class size of this institution is 239. The Department of Family Practice's current undergraduate curriculum involvement includes responsibility for 130 students in the Phase A program for one-half day per week throughout the year providing instruction in the introduction to clinical medicine, interview techniques and history taking, physical diagnosis, and the initial history and physical examination of patients. All students in Phase B spend one day per month with a practicing

TABLE 1
University of Minnesota
Medical School
Undergraduate Curriculum

cing family physician throughout nine months of their Phase B experience.

The Department of Family Practice recruits preceptors and coordinates this program.

In Phase D, the Department of Family Practice is responsible for the implementation of the Rural Physician Associate Program which currently has 38 students in rural areas throughout the state for a full year experience. Last year 23 students participated in this program. This is a combined education-service program. The physician preceptor pays the student \$5,000 and the university, through appropriated funds, pays the student \$5,000 for a total of \$10,000 for the year. The student becomes intimately involved in patient care with his preceptor during this period of time and returns to the University for an additional three calendar quarters of electives prior to receiving his M.D. degree.

The Department has also been active in the development, organization, and coordination of the preceptorship program in which students are sent out with both rural and metropolitan physicians for a period of six weeks during their Phase D program. Last year, some 64 students were out for this experience and this year it would appear that some 80 students will be participating. Eighty-three of the current Phase D students are lacking in Family Practice, and the department assumes the responsibility for advising these students in their curriculum planning.

Graduate Education Program

The Department of Family Practice and Community Health is responsible for the Affiliated Community Hospital Training Program in Family Practice. The major objective of this program is to train family physicians capable of giving continuing and comprehensive care, which includes the ability to apply this continuing care in a manner which gives appropriate recognition to the individual patient's life-style and relationship with his family and community. This comprehensive responsibility requires knowledge of and the ability to coordinate community health services.

This major objective clearly implies not only the provision of a training program designed to produce a physician of competence within the additional disease and organ oriented areas of patient care, but must provide for the acquisition of a body of knowledge within the behavioral sciences, allowing the student to function in this

comprehensive role.

Emphasis is placed upon developing expertise in common disease and health problems and in emergent care. Stress will be placed upon the diseases and problems which are most common to the ambulatory patients as well as the more common disease entities which are traditionally seen in the hospitalized patient.

We in Minnesota have been fortunate to have our training program in Family Practice funded by the State Legislature. Such financial support carries with it a very clear obligation to encourage the graduates of our training program to meet the needs of our own state and the areas immediately adjacent, for which the University of Minnesota has traditionally accepted some degree of responsibility.

The rationale for the development of the University of Minnesota Affiliated Training Program in Family Practice is based upon the recognition that community hospital participation in such a training program would provide a patient population with common diseases and problems most appropriate to this type of training program. The community hospital also provides a staff of very competent physicians within the fields of Family Practice and the traditional specialties who are involved in the ongoing care of such patients.

The University Hospital provides a patient population much more likely to have more unusual, esoteric types of disease. It provides full time teaching faculty with indepth expertise in the many specialty and subspecialty fields and a resource of many other disciplines, both academic and clinical with which to supplement the training program curriculum.

The development of such a consortium under the direction of the University of Minnesota Department of Family Practice and Community Health offers the administrative opportunity to coordinate the resources of both the community and the University in the development and implementation of a training program in Family Practice. There is the additional advantage of being able to utilize the graduate education program as the basis of a model for developing and nourishing student interest in a career within the field of Family Practice.

The program was developed utilizing six community hospitals and the University of Minnesota Hospital. The institutions participating in this program at the present time are (Figure 2):

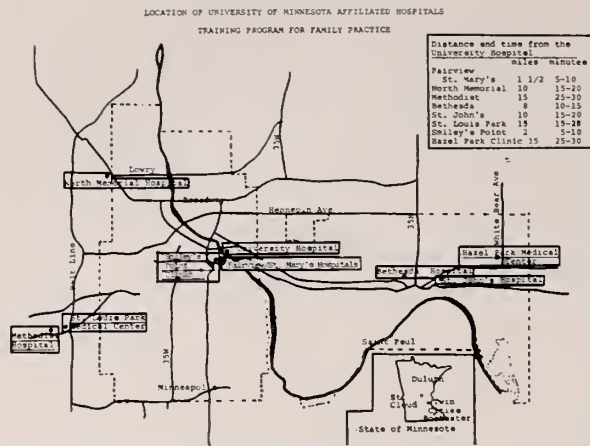

Figure 2

University Hospital	University of Minnesota Minneapolis, Minn. 55455
St. John's Hospital	403 Maria Avenue St. Paul, Minn. 55106
Bethesda Hospital	559 Capitol Blvd. St. Paul, Minn. 55101
Fairview Hospital	2312 South Sixth Street Minneapolis, Minn. 55406
St. Mary's Hospital	2414 South Seventh Street Minneapolis, Minn. 55406
Methodist Hospital	6500 Excelsior Blvd. Minneapolis, Minn. 55426
North Memorial Hospital	3220 Lowry Avenue North Minneapolis, Minn. 55422

Each of these institutions has developed or is in the process of developing a Model Family Practice Unit. The Model Family Practice Unit associated with the University of Minnesota is located within the University Hospital complex. The Model Family Practice Unit of St. John's Hospital is the Hazel Park Medical Center located at 933 White Bear Avenue, St. Paul, Minnesota, a distance of approximately five miles from St. John's Hospital. The Bethesda Hospital has established a Model Family Practice Clinic on the sixth floor of the hospital in a remodeled, abandoned, surgical suite. St. Mary's and Fairview Hospitals have joined together to produce a single unit within our program with its Model Family Practice Clinic located one block from the hospital facility and known as Smiley's Point Clinic, located at 2200 Riverside Avenue, Minneapolis, Minnesota. Methodist Hospital utilizes the Department of Family Practice within the St. Louis Park Medical Center located at 5000 West 39th Street, St. Louis Park, Minnesota, a distance of one mile from the hospital. North Memorial Hospital is the most recent addition of community

hospitals to the University of Minnesota Affiliated Training Program in Family Practice. They have not as yet developed their Model Family Practice Unit. This unit will be located near the hospital and will be completed in the Spring of 1973. Currently, only first year residents are located at North Memorial Hospital and these residents will start their half-day participation in the Model Family Practice Unit at the time of its completion. The geographic location and distances between these institutions are noted in Figure 2.

Each of these institutions function as a semi-autonomous unit having home-based residents assigned to them for the three year training program in Family Practice (three years following completion of M.D. requirements). The residents develop a continuing relationship to the patients within their own Model Family Practice Units and rotate out of their home-base hospitals and units on infrequent occasions.

During the resident's training program of three years duration (36 months) his assignments are as follows:

Internal Medicine & medical specialties	9	months
Pediatrics	4	months
Surgery & surgery specialties	6	months
OB/GYN	3	months
Model Family Practice Unit	18	months
Psychiatry	1	month
Emergency Room	1	month
Electives	1.5	month
Vacation	1.5	month
		<hr/>
		36.0 months

It is recognized that there is considerable overlap in many of these areas and the arbitrary time assignments do not necessarily accurately reflect emphasis, i.e., much internal medicine is applicable to pediatrics. In addition the Model Family Practice Unit teaching does directly relate to many of the traditional specialties. Much of the time in the last two years (18 months) is actually assigned in half day rather than full day blocks (Figure 3).

During the year 1971-72, 34 residents were in training within the Affiliated Community Hospital Training Program. This year some 50 residents have been training within the program. The distribution of these residents is demonstrated in Table 2. The graduate education program (residency program) also has several unique efforts

FAMILY PRACTICE

This outline indicates emphasis in terms of time commitments and does not present actual sequence of educational elements.

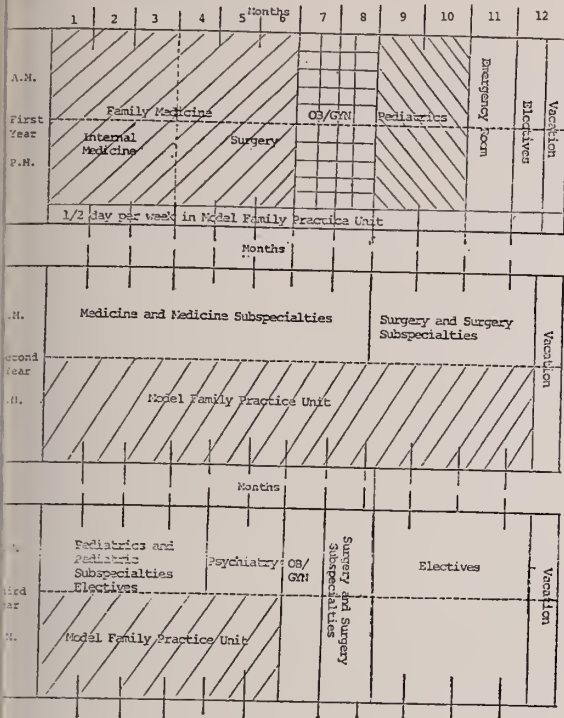

Figure 3

connected with it which are of interest.

1. Several of the hospitals have made available student clerkships for Senior students of medical schools other than the University of Minnesota which in effect brings graduates of other medical schools into the State of Minnesota.
2. The Department of Family Practice has arranged preceptorships for students of other medical schools with physician preceptors within the State of Minnesota.

Both of the above mechanism tend to develop interest in a medical career within the State of Minnesota for students who have not been trained at the expense of the State of Minnesota.

3. We have initiated an experimental rehabilitation program by accepting a physician for re-training following a severe bout of mental illness. The purpose of this program is to rehabilitate physicians who may have become

incapacitated due to alcoholism or other drug problems, mental illness and in some instances perhaps physical incapacitation.

Each of these efforts are directed towards the economical production or conservation of physician services within the State. The University of Minnesota Department of Family Practice and Community Health is academically related to Hennepin County General Hospital's Department of Family Practice and St. Paul Ramsey's Department of Family Practice. In each instance, the faculties of these two institutions are members of the faculty of the Department at the University. The residency training programs in Family Practice of our three institutions will have an annual output of approximately 60 physicians per year.

Summary

The health care needs of the State of Minnesota will require an acquisition of 125 new family physicians annually for the next ten years. The University of Minnesota Department of Family Practice and Community Health has assumed a responsibility to maintain and stimulate student interest in a career in Family Practice. The Department, together with the residency training programs at Hennepin County General Hospital and St. Paul Ramsey Hospital will reach an annual output potential of 60 family physicians per year in 1975. The feasibility of additional training programs for Family Practice or new mechanisms to attract family physicians to the State should be exploited.

Dr. Dean Fleming Honored

Dr. Dean S. Fleming, Hopkins has been honored by the Minnesota Respiratory Health Association with the Herman Kleinman Award.

The award was presented recently at the annual membership meeting of the state Christmas Seal Association.

Dr. Fleming is director of the Division of Disease Prevention and Control of the Minnesota Department of Health.

The Commercial Boundaries of Rural Communities

STEPHEN NYE BARTON* and JOHN O'LEARY, M.D.†

THE BUSY PHYSICIAN is aware that patients from one locality will tend to seek his services while those from another area may go elsewhere. Patients who travel to a community seeking goods and services may follow the same routes when seeking medical care. A knowledge of trade boundaries and traffic flow patterns is of value to the physician or group considering a rural practice. In Southwestern Minnesota six doctorless communities seeking a physician participated in a project to identify potential health service geographic patterns: Jeffers, Lamberton, Revere,

Storden, Wabasso, and Wanda.

Commercial Survey

In 1913 Galpin identified trade boundaries in rural communities by asking local merchants to locate their customers on a county map. He suggested that the "trade zone" of a town was the real boundary of a "community."¹ The work of Kolb and Day concluded that general trade was the best method of delineating the boundary of a community.²

In the present study a modified Galpin approach was used to analyze business trade area perimeters. A map was mailed to every known business in the study area with instructions to draw lines encompassing the source of 90% and

*Senior medical student at the University of Minnesota Medical School and Research Associate in the Department of Family Practice and Community Health.

†Associate Professor, Department of Family Practice and Community Health, University of Minnesota.

Fig. 1—Revere composite trade configuration; 50% perimeter.

Fig. 2—Commercial boundaries of six rural communities; 50% perimeter.

50% of the customers. A demonstration map with sample trade perimeters was included so that the businessman would understand precisely what was desired. Survey cooperation was enhanced by identifying a representative from each of the six communities in a cover letter. Of the 104 businesses surveyed 72 responded.

A composite map for each town was created by tracing each business perimeter onto a common map for its town. Only the 50% perimeter was included for the purpose of this analysis. A composite map for Revere is shown in Figure 1. As anticipated, the trade perimeters were irregular.

A summary trade map was constructed to identify the trade configuration relationships between the six communities. The map was made by taking the greatest possible trade perimeter for each of the six communities with the requirement that at least two businesses identified the territory within the perimeter at a given point as being the source of customers within their 50% trade perimeter (Figure 2).

Traffic Flow Patterns

An understanding of traffic flow patterns is crucial in identifying natural trade routes. Haga and Folse in a survey of rural villages in central Illinois concluded that as village size decreased, improved roads influenced trade patterns.³ To understand the relationship of the six communities to surrounding resources, traffic flow patterns in Southwest Minnesota were analyzed.

State and county traffic flow maps are available from the Minnesota Department of Highways. The change in the quantity of traffic flow is indicated by shaded areas over the roads; the greater the width of the shaded area, the greater the traffic flow. Individual traffic flow counts are available for all highways and roads in the state of Minnesota.

The graphic description of traffic flow for

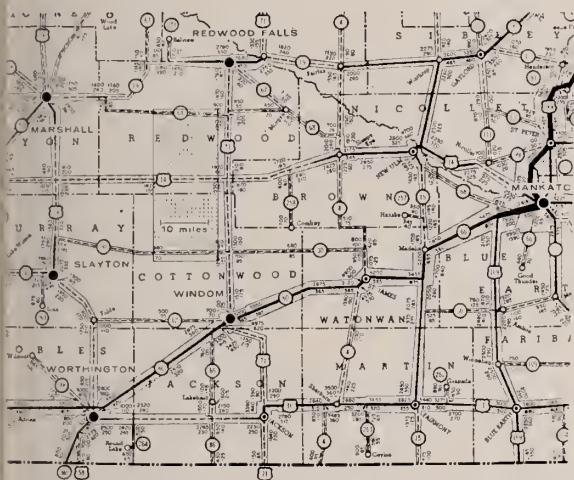

Fig. 3—Traffic flow in Southwestern Minnesota

Fig. 4—Traffic flow towards Redwood Falls.

Fig. 5—Traffic flow towards Windom.

southwestern Minnesota (Figure 3) reveals that the six communities are central to four traffic flow centers: Marshall and Redwood Falls are hubs north of the six communities; Slayton and Windom are hubs to the south. On major highways in Southwestern Minnesota traffic builds from west to east towards Mankato and Minneapolis.

County traffic flow maps indicated that Lamberton had the greatest average traffic flow of the six communities. Traffic flow increased from Wabasso towards Redwood Falls to the north

(Figure 4); and from Storden and Jeffers to Windom in the south (Figure 5).

Conclusion

Two methods for identifying the dynamic boundaries of rural trade areas have been described. Commercial trade surveys and traffic flow analysis may be used to identify dynamic relationships between communities and potential health service geographic patterns or trends. These techniques will aid primary care physicians considering rural locations for practicing medicine.

Suddenly a palsied chill
Struck from the paved level up my limbs,
And was ascending quick to put cold grasp
Upon those streams that pulse beside the throat:
I shriek'd, and the sharp anguish of my shriek
Stung my own ears—I strove hard to escape
The numbness; strove to gain the lowest step.
Slow, heavy, deadly was my pace: the cold
Grew stifling, suffocating, at the heart;
And when I clasp'd my hands I felt them not.
One minute before death, my iced foot touch'd
The lowest stair; and as it touch'd, life seem'd
To pour in at the toes: I mounted up.*

The New Curriculum at the Minneapolis Campus

A Description and Preliminary Report

ROBERT J. McCOLLISTER, M.D.*

BY JUNE, 1973, THE first full class of medical students will have completed all requirements of the new curriculum of the University of Minnesota Medical School at Minneapolis. The new program has been a central concern of the faculty for more than six years requiring planning, revising, teaching, evaluating, and comparing. This paper describes how the program came about, outlines the features of the curriculum, and presents preliminary information on the achievement of the students who have constituted the inaugural class.

In 1964 the Constitution governing the organization of the Medical School was approved. The Educational Policy Committee,[†] was charged with the responsibility for curriculum planning and evaluation, and set to work gathering information on curricula at other schools, discussing the future of health care and medical practice and hearing from a wide variety of interested individuals and groups. Faculty retreats, extensive discussion with students, faculty, physicians in full-time practice and others were an integral part of the process essential to develop the revised program. Nearly three years elapsed from the start of the Committee's work to the fall of 1969 and the inauguration of the revised curriculum.

The Committee endorsed four goals which influenced later planning: (1) flexibility, (2) student as learner, (3) relevance, (4) improved faculty communication. Three goals relate directly to the needs of medical students now in training: "flexibility," because students come to medical school from diverse educational backgrounds and go on to a variety of career goals; "student as learner" to focus on the key aspect of the educational process, the student and his attitude toward medical education as a self-initiated, self-directed process, to become a lifetime professional habit; and "relevance," to be mindful of the need for continuing critical review of burgeoning scientific

information to identify core knowledge essential in preparation for medical practice. The fourth goal, "improved faculty communication," is viewed as a means to enhance the educational process through exchange and understanding among the faculty and between students and faculty.

The curriculum plan devised to promote these goals was outlined at the outset, in Phases. This term was chosen because Phase did not connote a particular time limit. In the latest modification of the new plan, Phase A and Phase B each require one calendar year for completion.

Phase A is four quarters in length, extending from fall to early August (Figure 1). The traditional basic medical science subjects are included in this Phase: anatomy, biochemistry, microbiology, pathology, physiology and introductory pharmacology. In addition, students are introduced to clinical medicine by means of small group sessions on patient care, history taking and physical diagnosis, the latter in the third and fourth quarters. A course in behavioral science related to medicine is included early in Phase A. To provide an opportunity for students to discuss their problems relating to the curriculum program, medicine and society, or to personal concerns, small group discussion sessions are available on an optional basis. The student completing Phase A should possess a wealth of basic

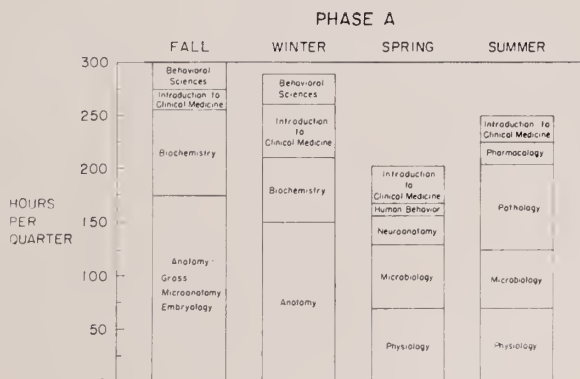

Figure 1

[†]Drs. Richard Ebert (Chairman), Richard Varco (Vice-Chairman), Wallace Armstrong, Ellis Benson, Eugene Grim, Donald Hastings, Carl Heggstad, Robert Ulstrom, Dennis Watson, H. M. Savert (ex-officio), R. J. McCollister (ex-officio).

scientific knowledge together with suitable attitudes and skills to facilitate his pursuit of advanced medical knowledge at the bedside.

Phase B (Figure 2) represents the sharpest departure from the traditional arrangement of a second year in medical school. Phase B didactic teaching is organized along organ or system lines, with responsibility delegated to interdisciplinary teaching committees rather than to departments. The teaching committees are assigned core hours, ranging from 17 to 50 or more, depending on subject area. These multidisciplinary committees identify course objectives, plan presentations, and evaluate student performance. Most committees have developed syllabuses which represent the core content of the subject area. In addition, the committees develop optional activities for unscheduled time. The clinical experiences in Phase B have been organized within a single course, "Student as Physician," which extends through the four quarters of the Phase. Students participate in hospital, outpatient and office medical care in groups of two or three under tutors. Students are assigned patients in medicine, pediatrics, family practice, surgery, physical medicine and rehabilitation, obstetrics-gynecology, neurology and psychiatry. During these successive assignments the student studies intensively 50 to 100 patients with a variety of medical problems. Tutors are recruited from the full-time and part-time faculty. In family practice, surgery and obstetrics-gynecology tutorials, physicians in full-time practice con-

tribute a major share of the teaching effort. By the time the student completes Phase B, he will have been in medical school eight quarters, the equivalent of a status midway through the junior clerkships in the old program. He will have completed nearly all of the formal didactic work, will be prepared to pass Part I of the National Board and will have had experience in all major specialty areas. The student should be prepared to assume responsibility in the full-time clinical courses in the next Phase.

Phase D is organized along pathways of interest designated tracks: medicine and pediatrics, medical specialties including obstetrics, family medicine, surgical specialties, neurological sciences, psychiatry-behavioral science and basic medical science, (Figure 3). During the last quarter of Phase B, the students begin to plan their Phase D programs. This involves first, a choice of track of interest and an advisor. In each track, courses are strongly recommended for inclusion in the individual's program. For example, students in the medicine track are counseled to include, as a minimum, six-week externships in medicine, surgery, neurology and obstetrics-gynecology in their Phase D plans. All track recommendations include externships in medicine and surgery and all include a component of basic science courses. Thus, there is considerable overlap among the several tracks in the strongly recommended components.

This curriculum permits a student to complete medical school in eleven quarters: eight quarters in Phases A and B plus three quarters of Phase D work. This is designated the three-year option. Most students have not availed themselves of this accelerated program, preferring instead a four-year program, with 13 total quarters of work and

Figure 2

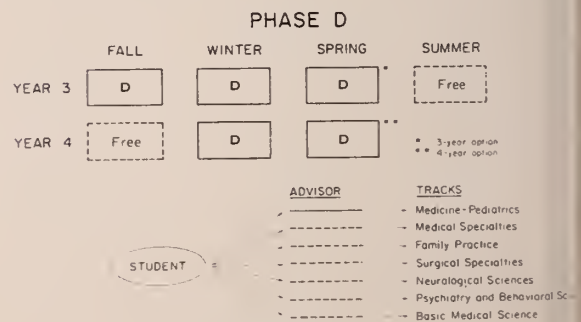

Figure 3

quarters of free time. Figure 4 shows one of several possible arrangements of the four-year program.

By June of 1973, the first class completing the new curriculum will be graduated. Thirty-one of the entering class of 162 elected to graduate in June of 1972, after completing three quarters of Phase D. Their classmates who remained for an additional year took a variety of programs: some took the third year on the Rural Physician Association Program and are now completing the three additional required quarters of Phase D courses, while others took an assortment of courses, interspersed with free time.

All preliminary evaluations of the students' performance indicate satisfactory achievement, in comparison with those of former years. On the Part I test of the National Board of Medical Examiners, students achieved a higher average level of performance in five of the six subtests and remained at the same level in one, with an average percentile increase in the class score on the total test at nearly 10 percent, when compared with the old curriculum students who took Part I test one year earlier.

On Part II of the National Boards, only preliminary information is available, since many students will not take this until spring, 1973. But 31 students who graduated on the shorter,

optional program in 1972 took this test as required, before graduating and they did as well, on the total test, as did the students who graduated under the old curriculum after completing four years' study. The accelerated graduates were a self-selected group and in many ways not comparable. Nonetheless, the new curriculum students were afforded the opportunity to accelerate, took it and did well by the Part II standard of comparison.

In ratings of the new curriculum students on clinical performance in full-time externship duties, evaluations have been comparable to old curriculum students. A comparison of students from the new curriculum with the old, working side by side in externships in medicine, surgery, pediatrics and obstetrics-gynecology fall and winter, 1971-72, showed them significantly better with patient records, case presentations and use of the library. In "histories" and "physicals" in the obstetrics-gynecology program, the old curriculum students did significantly better. Students who had come along through the clerkship system were better prepared for externships in this specialty. There were no statistically significant differences in level of performance of the old curriculum four-year and new curriculum four-year students in 16 categories rated when all specialties and periods were combined. Table 1 shows the comparison between the groups of students in the several categories rated.

The competition for internships is another area in which the new curriculum group may be meas-

ured. The final data for the entire first class is not yet available; however, of the 31 students who went on to internships in June, 1972, the pattern of hospitals to which the students matched was comparable to the other 1972 graduates. In Table 2, the two groups are compared.

The years 1969-73 have been a time of curriculum change and intensive evaluation. Studies of new curriculum student performance on National Board tests, clinical work and internship choice have provided data for comparisons between the new and old curriculum students. Those on the new program have earned better basic science board scores and have done better in some aspects

of clinical work. The results to date represent an encouraging first stage of a comprehensive evaluation of this new program.

The city lies sleeping;
The morn, to deplore it,
May dawn on it weeping:
Sullenly, slowly,
The black plague flew o'er it—
Thousands lie lowly;
Tens of thousands shall perish;
The living shall fly from
The sick they should cherish;
But nothing can vanquish
The touch that they die from.*

Minnesota Graduates: 1896 to 1971

JUDITH GARRARD, PH.D.*

By 1971, the number of living graduates of the University of Minnesota Medical School had grown to over five thousand individuals. Demographic information about these graduates would be helpful in planning undergraduate curriculum changes and in assessing the impact of these changes on future graduates. In June 1971, data concerning geographical location, type of practice, and specialty of all living graduates were obtained by the Medical School from the American Medical Association. A summary of this information is described here.

Postgraduate Training

Practically all graduates since 1896 have had internship training. Half (48%) of these internships have been in Minnesota, with the majority at three major Twin Cities hospitals: Hennepin County General, University of Minnesota, and St. Paul Ramsey.

Residency training has been taken by fifty-five percent of the Minnesota graduates over the past 75 years. Like the distribution of internships,

half of the residencies have been in Minnesota. The Veteran's Administration and University of Minnesota Hospitals have been the two major residency training centers of Minnesota graduates.

Distribution of Physicians

Although Minnesota graduates are currently practicing in all fifty states, 47% are located in Minnesota (Table 1). This compares favorably with the national average: In 1967, 43% of the graduates of all U.S. medical schools were located in the state of their medical school graduation.¹

There appears to be a strong relationship between location of current practice and location of postgraduate training. As shown in Table 2, two-thirds of the graduates currently located in Minnesota took their internships here; whereas only one-third of the Minnesota graduates practicing elsewhere took their internship in Minnesota. The contrast is even greater with regard to residency training. Of the graduates currently practicing in other states, 27% took a Minnesota residency; whereas, 80% of the Minnesota based graduates took residencies in this state.

Table 3 summarizes the distribution of Minnesota physicians in metropolitan and non-metropolitan counties. This shows that the majority of all Minnesota physicians, regardless of medical school background, are in the major metropolitan counties (Anoka, Carver, Dakota, Hennepin, Olmsted, Ramsey, St. Louis, Scott, and Washington). A greater proportion (24%) of the Minnesota graduates practice in the non-metropolitan counties in Minnesota than do graduates of other medical schools (15%).

The distribution of physicians by size of town

*Curriculum Evaluator, Medical School, and Assistant Professor, Department of Physical Medicine and Rehabilitation, University of Minnesota Medical School, Minneapolis, Minnesota. This research was supported in part by NIH Grant No. 18 ME 00109 02.

§AMA: Distribution of Physicians in the U.S., December, 1971.

is given in Table 4. Here the data show that 25% of the Minnesota graduates practicing in Minnesota are in towns with a resident population of 25,000 or less. Comparative data for non-Minnesota graduates are not currently available.

Distributions of physicians by type of practice are given in Table 5 for physicians throughout the U.S., in Minnesota (regardless of medical school background) and for Minnesota graduates. A separate category for Family Practice is not listed by the American Medical Association in its most recent publication of physician distribution;² therefore, in this analysis, Family Practice and General Practice are combined.

Thirty-three percent of the Minnesota graduates currently located in Minnesota identify themselves as being in General or Family Practice. This is considerably higher than the national average of 17% of all U.S. physicians or that of 21% of the

physicians in Minnesota (regardless of medical school background).

Data regarding the different specialties recognized by AMA and categorized as medical, surgical, or other are also given in Table 5. In general, the differences among physicians in the U.S. and Minnesota compared with Minnesota graduates are not as striking as in the general or family practice category.

Thirty-nine percent of all Minnesota graduates have been certified by one or more of the American Specialty Boards. This is comparable to the national average of 34% of all U.S. medical school graduates.¹ The data reported in Table 5 are the number of certifications granted, which is greater than the number of physicians who received certification. For example, 83 Minnesota graduates are certified in two specialties. The number of certifications is comparable between U.S. physicians and Minnesota graduates within each of the specialties.

Summary

This report summarizes the professional characteristics of all living graduates of the University of Minnesota Medical School from 1896 to 1971. The information described here includes geographical location by state, county, and size of city, location of internship and residency training, type of general specialty practice, and certification by an American Specialty Board. These data were obtained by the Medical School from the AMA in June, 1971, for purposes of educational planning and future evaluation of the undergraduate medical curriculum.

History of Medicine

The Drama of Sulfanilamide, Penicillin and other Antibiotics 1936-1972

WESLEY W. SPINK, M.D.*

WAR, FAMINE and pestilence have always tormented mankind. One of the most beneficial accomplishments in medical history has been the control of infectious diseases during the last one hundred years, and within the past forty the most dramatic therapeutic advances have occurred. I have been primarily engaged in the study and management of infections for more than these forty years, thirty-six of which have been centered at the University of Minnesota Hospital.

I propose to narrate some of the major achievements, to point out some remaining challenges and to conclude with some of the problems created by this advance.

Evolution of Control of Infectious Diseases

No infectious disease has ever been treated out of existence. The key word in the control and eradication of specific infections has been and remains, *prevention*. The evolution of successful control can be discussed under three headings.

First, during the course of human history and long before the emergence of the germ theory of disease, epidemic diseases such as leprosy, plague, smallpox, syphilis, yellow fever and dysentery were considered to be contagious. To meet the challenge, severe quarantine regulations involving international commerce were set up as early as the fifteenth century and not without success. A marked advance occurred in the nineteenth century, induced in great part by the industrial revolution. Although largely ignoring the concept of contagium at times, a spirit of humanitarianism and social reform appeared and resulted in such measures as improved housing, better nutrition, proper sewage disposal, available pure water supplies and the regulation of child labor. During this period good health revolved around changing social, economic and political attitudes.

Second, the explosion of microbiology in the nineteenth century led to the discovery of the specific cause of disease to more intelligent preventive measures in the form of vaccines and to effective therapy with antisera. The spread of disease by insects and animals was also recognized and this knowledge further enlightened efforts toward prevention.

Third, largely through the genius of Paul Ehrlich, the science of chemotherapy and chemoprophylaxis made great strides, especially just before and during World War II. The sulfonamides and antibiotics were introduced for therapy, and insecticides and pesticides as prophylactic agents. I shall dwell largely on this third aspect of the control of infectious diseases since I lived through it and participated in some of the early adventures.

Early Personal Involvement

Since this is largely a personal narrative let me present my introduction to infectious diseases. As a medical student at Harvard in 1929 I fell under the spell of one of the greatest of teachers, Dr. Hans Zinsser, Chairman of the Department of Bacteriology and Immunology. From then on my basic interest was in infectious diseases and internal medicine.

For seven years I engaged in patient care and research in one of the country's largest hospitals in Boston. The leading cause of death was pneumonia. My research centered around streptococcal diseases and gonorrhea, both devastating infections of man. At that time specific treatment for infectious diseases was very limited. It consisted of immune sera for certain types of pneumonia and diphtheria and Ehrlich's arsphenamine, a drug for syphilis that was quite toxic. All of us shared in the depression over the lack of specific treatment.

In 1936, Dr. Perrin Long of Johns Hopkins Hospital, who had completed his training in Boston just before my tenure, told us about the observations of Domagk in Germany in curing streptococcal disease with a red dye, a chemical that turned out to have p-amino benzene sulfonamide, or sulfanilamide, as its active component. Through Dr.

*Wesley W. Spink, M.D., is Professor of Medicine and Comparative Medicine, University of Minnesota Medical School, Minneapolis. He presented at an All-University Convocation on April 11, 1973, University of Minnesota, Minneapolis. This publication was supported by NIH Grant No. 1 F13 6, 415-01 from the National Library of Medicine. See editorial, page 509.

Long, the late Dr. Chester Keefer and I soon had sulfanilamide in Boston, and we were impressed with our results in both streptococcal disease and in gonorrhea.

Shortly thereafter, on August 1, 1937, I joined the faculty of the University of Minnesota and the staff of the University Hospital, arriving with sulfanilamide "in my back pocket." During the next few years I was encouraged to evaluate the drug throughout the hospital.

On the evening of February 2, 1939 I presented a Sigma Xi Lecture in Northrop Auditorium on "Sulfanilamide and Related Chemicals in the Treatment of Infectious Diseases" (Figure 1). This was a part of a series of lectures on "Recent Developments in Medical Science" celebrating the Fiftieth Anniversary of the Medical School. I gave details of the therapeutic results in several hundred patients, stressing those with pneumonia, streptococcal disease, gonorrhea, suppurative meningitis, and urinary tract infections,¹ and it also resulted in my preparing a monograph on the subject.² The years 1937 to 1942 were exciting because we were living in a new era in medicine.

Fig. 1—Poster announcing Sigma Xi Lecture on February 2, 1939 in Northrop Auditorium. Note that the lectures were preceded by music.

Experiences shared by many of us had revealed at the time of the onset of World War II that the sulfonamide drugs had therapeutic shortcomings. There were many infectious diseases that did not respond to this therapy, especially staphylococcal diseases. Furthermore strains of hemolytic streptococci and gonococci had become resistant to sulfonamides, and there existed the possibility that uncontrolled epidemics of streptococcal infections and gonorrhea could appear among military per-

sonnel if other agents did not become available. This apprehension became a reality. As a member of the Hemolytic Streptococcus Commission of the Armed Forces Epidemiological Board I saw hundreds of cases of streptococcal disease, including rheumatic fever, in U. S. Army troops. Fortunately, penicillin had just been made available, though in limited amounts.

Penicillin

The successful development of the antibiotic penicillin, was a product of cooperative effort during World War II. Today, penicillin remains the grandfather of antibiotics and along with its close related derivatives, the agent having the widest application in the treatment of disease.

Penicillin was discovered by Sir Alexander Fleming and described by him in his publication of 1929: "On the antibacterial action of cultures of *Penicillium* with special reference to their use for the isolation of *B. influenzae*"³ (Figure 2). It was an accidental discovery. Working in his small laboratory at St. Mary's Hospital in London he had placed aside a culture plate with colonies of staphylococci on its surface. Weeks later examination of the plate remaining on his bench revealed that the colonies of staphylococci adjacent to the growth of a contaminating fungus, *Penicillium notatum*, had been destroyed, or lysed. Fleming appreciated the significance of this natural phenomenon. He prepared an extract of the fungus called it penicillin, and noted that it inhibited the growth of other bacterial species. Furthermore the agent was not toxic when injected into animals. Dr. Ronald Hare, a contemporary of Fleming's at St. Mary's Hospital, in writing on the history of penicillin stated, "it was, surely, the supreme example in all scientific history, of the part that luck may play in the advancement of knowledge." However, Fleming's finding escaped the attention of most investigators until a decade later when Sir Howard Florey and his associates at Oxford

ON THE ANTIBACTERIAL ACTION OF CULTURES OF A
PENICILLIUM, WITH SPECIAL REFERENCE TO THEIR
USE IN THE ISOLATION OF *B. INFLUENZAE*.

ALEXANDER FLEMING, F.R.C.S.

From the Laboratories of the Inoculation Department, St. Mary's Hospital, London.

Fig. 2—Reprint of Fleming's first paper on penicillin presented to the author by Sir Alexander. This is a collector's item because of its rarity.

University undertook to isolate penicillin and to extend his observations.

The discovery of Fleming may have been a matter of sheer luck, but his mind had been well prepared for it. Serving with the British Army in France during World War I, he was disturbed by the lack of acceptable antimicrobial substances for wound sepsis. He knew that although certain chemicals destroyed microorganisms, tissue cells were injured as well. The ideal agent ought to eradicate the bacteria without having a toxic effect in the blood or tissues of the host. He brooded on his problem, and several years before his momentous discovery of penicillin he reported that lysozyme obtained from tears, nasal secretion, and egg white was the ideal substance he was looking for.⁵ Florey also recognized this finding of Fleming's. Fleming's techniques were original and extremely simple. In 1954 he came to our laboratory at Minnesota and showed us his techniques in working with penicillin (Figure 3).

When Great Britain became embroiled in World War II the problem of wound sepsis engaged the attention of Florey and his associates

at Oxford. He had had a long-time interest in lysozyme, and as a part of the war effort in the search for an antimicrobial agent he turned to Fleming's penicillin. The most challenging and difficult problem was the extraction of adequate amounts of active penicillin for experimental purposes. But sufficient quantities were finally obtained, and the results of his experiments were published in 1940 under the title of "Penicillin as a Chemotherapeutic Agent"⁶ in a paper of three pages and headed by six authors (Figure 4)! Subsequently, two of these authors, along with Fleming, were awarded the Nobel Prize in Medicine.

PENICILLIN AS A CHEMOTHERAPEUTIC AGENT

BY

E. CHAIN, PH.D. CAMB.	M. A. JENNINGS, B.M. OXF.

(From the Sir William Dunn School of Pathology, Oxford)

THE LANCET 239:226-228, Aug. 24, 1940

Fig. 4—First publication of Oxford Team on penicillin. Florey and Chain received the Nobel Prize with Sir Alexander Fleming.

I knew nothing of Fleming's report, and the paper of Florey and his associates had escaped the attention of most of us because we were engrossed in studies on the sulfonamides, and also because of the war. My first knowledge of penicillin came in a most dramatic manner. One day late in the summer of 1941 I received a phone call from my friend and associate, Dr. Owen Wangenstein, asking if I would join him and a few others at a dinner for Dr. Howard Florey of Oxford. That evening in Minneapolis the story of penicillin was quickly unfolded to us. The penicillin prepared for human subjects had been first administered by a team that included his physician-wife, Dr. Ethel Florey. England was being bombed, and there was no opportunity for Britain to engage in the complicated commercial production of penicillin. Florey was in this country to enlist the Government of the United States and the pharmaceutical industry to produce the antibiotic. The office of Scientific Research and Development established by President Franklin Roosevelt responded to this appeal, and the production of penicillin by 1943 on a large scale is a tribute to a cooperative effort on the part of government and industry.

Fig. 3—Photograph of Sir Alexander (on the left) and the author taken in 1954 at University of Minnesota Medical Center.

As with my contacts with Alexander Fleming, those with Professor Howard Florey continued. After the war I met with him and his associates at Oxford. At that time, a few of us were concerned about a therapeutic problem with penicillin, specifically, the appearance in patients of strains of staphylococci resistant to the action of penicillin. Later Dr. Ethel Florey, then Lady Florey, joined us in our laboratory at Minnesota to explore this problem. Sir Howard Florey was not only a brilliant scientist but an excellent administrator and leader. More formal and restrained than Sir Alexander Fleming, he was generous and most forthright in his analysis of any problem. He ended his career as Lord Florey and Provost at Oxford University.

Trickles of penicillin became available for investigation in 1942 under a Committee of the National Research Council headed by Dr. Chester S. Keefer. We were assigned the task of evaluating the antibiotic in staphylococcal infections. Staphylococcal septicemia carried a mortality rate of 80%, and we had accepted a severe challenge at the University Hospitals. There were few or no guidelines for either the administration of penicillin or of its over-all effects. Our purpose was to aid in the establishment of the basic principles for penicillin therapy.

On July 11, 1942, a seven-year-old girl extremely ill with staphylococcal bacteremia was given the first penicillin in our institution, and as I learned later, she was among the first in the nation to be treated in this manner. Her recovery was dramatic. From then on with my associate, Wendell Hall, up to 200 patients received penicillin from this governmental source without cost to them and with highly satisfactory results.⁷ By 1944 it was apparent that a new epoch in the management of sepsis and infectious diseases had arrived.

Wallace Herrell and his associates at the Mayo Clinic also pioneered in the clinical use of penicillin. Initially, they prepared their own crude penicillin for human use!⁸

Streptomycin

The discovery of penicillin and its successful application in the therapy of infections provided a stimulus to the search for similar antimicrobial agents that would be effective against those diseases for which penicillin was not useful. In 1944, Dr. Selman Waksman and his associates at Rutgers University announced the discovery of streptomycin, which was isolated from a fungus

found in the soil and called *Streptomyces griseus*. Once again the National Research Council and its appropriate committee began an intensive evaluation of this antibiotic.

In 1882, Robert Koch had discovered the germ of tuberculosis, and later Edward Livingston Trudeau, who established the first tuberculosis sanatorium in America at Saranac, New York, wrote "If I could learn to grow the tubercle bacillus outside of the body and produce tuberculosis and will with it in guinea pigs, the next step would be to find something that would kill the germ in the living animal. If an inoculated guinea pig could be cured, then in all probability this great burden of sickness could be lifted from the human race."

Trudeau's dream finally came true in 1942 when the beautiful experimental data of Feldman, Hinshaw and Mann of the Mayo Clinic proved that tuberculosis could be controlled with streptomycin in the highly susceptible guinea pig.¹¹ Over the succeeding years, human tuberculosis responded to streptomycin, and also to dihydrostreptomycin. One of the most outstanding cooperative therapeutic studies ever carried out was the streptomycin studies on tuberculosis by the U. S. Veterans Administration throughout its affiliated hospitals. The staff of the Minneapolis Veteran Hospital played an important role in this effort.

Our own interests in streptomycin were directed toward its possible use as a therapeutic agent for the treatment of brucellosis, or undulant fever, which was prevalent throughout Minnesota, and adjoining states. Neither the sulfonamides nor penicillin were effective. After extensive experimental studies we observed that a combination of streptomycin and sulfadiazine provided a successful therapeutic regime for this disabling disease.¹²

Although streptomycin was effective in other diseases, the drug was found to have two undesirable effects. First, it was toxic, causing damage to the nerve tissue of the ear resulting in dizziness and sometimes permanent loss of hearing. Second, following initiation of treatment bacteria often quickly became resistant to the destructive action of streptomycin. Thus the search continued, particularly by the pharmaceutical industry, for other antibiotics.

Aureomycin

As we reflected on the status of antibiotics in 1948 we hoped for that almost ideal antibiotic with the following characteristics: First, it should be readily administered orally; second, it should

active against a wide spectrum of organisms; and third, it should have minimum toxicity for the host. This was asking almost too much.

In view of our thinking we were surprised to receive as a visitor to our laboratory in 1948 Dr.

Subbarow, Director of Research at Lederle Laboratories. He had been my instructor in biochemistry in medical school. On this visit he told me about an antibiotic that appeared to have the characteristics just described. It was called Duo-gramin, later Aureomycin, or chlortetracycline. We carried out investigations in the laboratory against brucella with this drug and found that it did inhibit growth of the organisms. During the summer of 1948 under the auspices of the National Research Council, Washington, and the Government of Mexico, Dr. A. I. Braude and I carried out successful therapeutic studies with aureomycin in a group of patients seriously ill with chronic brucellosis in Mexico City. Chlortetracycline was the drug that we were looking for in the treatment of human brucellosis,¹³ and it still remains a drug of choice the world over, 25 years later.

Chlortetracycline does have a wide spectrum of antibacterial activity, and it is also of value in the therapy of the rickettsial diseases. It has been found useful for both urinary tract and pulmonary infections. The toxicity of chlortetracycline remains minimal, and resistance to this antibiotic has not been a serious problem.

Other Antibiotics

We now have three groups of semi-synthetic penicillins: Acid-stable preparations such as benzyl penicillin, those having anti-penicillinase activity, which aids in the resolution of the problem of penicillin-resistant strains of staphylococci, and those with a wider antibacterial spectrum such as ampicillin and carbenicillin. Newer antibiotics from different sources include kanamycin, streptomycin, polymyxin, erythromycin and gentamicin. The new cephalosporins include cephalexin and loridine. Again, one can note why penicillin and its relatives are still the greatest of all. They are inexpensive and relatively nontoxic.

It is appropriate at this juncture to cite some of the problems induced by antimicrobial therapy and to look into the future for other developments in the control and management of infectious diseases. While it is likely that epidemics will occur intermittently, especially in the less technologically advanced countries, the one epidemic disease that still poses a threat universally is influenza.

Some Side Effects of Antibiotic Agents

While we have succeeded in controlling and treating the majority of bacterial infections, society is faced with difficult social and medical problems, some of them induced by the agents that have measured our progress.

Prior to the antibiotic era pneumonia was considered to be the old man's friend. It eased him out of this life quickly and relieved him of untold suffering. Antibiotics have added to longevity. These added years are often associated with degenerative diseases, debility due to cerebrovascular accidents, heart disease, cancer, and metabolic disorders. A longer life too frequently is accompanied by neglect, poverty, inadequate medical care, depression and loneliness. This constitutes not only a medical problem but challenges our social order. In the United States today 25 million people are 65 years or older.

Whenever a drug has a wide therapeutic range, appears relatively nontoxic, and is inexpensive, it tends to be used indiscriminately, often with undesirable results. No available drug is devoid of harmful effects. Except under rare circumstances, self medication with antibiotics must be discouraged. First, uncritical therapy has contributed to the appearance of microbes that have become highly resistant to the antibacterial action of the drugs. This is particularly true of the staphylococcus which has become largely resistant to penicillin, and to enteric organisms which have become resistant to other antibiotics. Second, these drugs do have serious side effects, which at times may lead to death or to a state of drug allergy that may prohibit their indicated use for a subsequent serious infection.

What of the Future?

Many basic investigations and therapeutic endeavors will continue to revolve around the viruses. Two outstanding achievements during the few decades in viral research have led to remarkable successes. First, physicists, biochemists and biologists joining forces have added to our vast knowledge in molecular genetics. Studies at a molecular level have yielded information relating to basic cellular activity, including antigen-antibody immune relationships. There is accumulating information indicating that viruses are implicated in at least some forms of malignancy in animals, and possibly in man. One can also speculate that molecular biology will not only advance our

knowledge of viruses and cells in general, but may be utilized in more precise studies on animal and human behavior.

A breakthrough in studies in virology has been the successful growth of large quantities of pure viruses in tissue cultures. As a result many important vaccines have been produced, among them those for poliomyelitis, measles, mumps and German measles.

It is difficult to predict the future for antiviral drug therapy, but it is not unlikely that experimental models will be set up embracing the virus in the disciplines of molecular biology and molecular pharmacology. The important studies on cell membranes have certain implications along these lines, and perhaps out of this combined approach suitable antiviral agents will evolve.

Conclusion

The dramatic impact upon the control of infectious diseases made along the three lines of attack at the beginning of this article is reflected in the marked decline in the incidence and mortality rates from these diseases on a national and state level. Figure 5 illustrates the marked reduction in the incidence of infectious diseases in Minnesota during the past few decades.

After meeting the challenge of infectious diseases for over 40 years, I am now ready to step down and pass the opportunities on to younger hands. I would say to all of you: be ready to meet the opportunity that confronts you so that you, too, may enjoy the drama of the sudden appearance of new knowledge that will contribute to the relief of human suffering.

In Memoriam

FREDERICK HAROLD POPPE, M.D.

Dr. Frederick H. Poppe, 90, died February 15, at Miami where he had retired after practicing medicine 50 years. A graduate of the University of Minnesota Medical School and a former professor at the University, Dr. Poppe specialized in surgery in Minneapolis. He was a member of the Hennepin County Medical Society and the American Medical Association and a Life and 50 Club Member of the Minnesota State Medical Association.

Dr. Poppe is survived by his wife, Irma, daughters, Annifred and Diana, and sons, Dr. Frederick P. Poppe and Rev. H. Poppe.

DONALD V. JORDAN, M.D.

Dr. Donald V. Jordan, 73, Minneapolis physician, died February 18. He graduated from the University of Illinois Medical School in 1928.

Dr. Jordan was a member of the Minnesota State Medical Association, Hennepin County Medical Society, American Medical Association and Minnesota Historical Society.

He had no immediate survivors.

ROGER S. COUNTRYMAN, M.D.

Dr. Roger S. Countryman, St. Paul physician, died February 20 in Saratoga, California, where he had been residing since his retirement. He attended the University of Minnesota, graduating in 1920, and moved into his residency in obstetrics and gynecology at Vancouver General Hospital in Canada.

During his private practice in the Twin Cities, Dr. Countryman served as Director of the Prenatal Clinic at the Wilder Dispensary and Chief of the Obstetrical Services at the Charles T. Miller Hospital. He was a member of the Ramsey County Medical Society and American Medical Association and an Associate and Life Member of the Minnesota State Medical Association.

Dr. Countryman is survived by his wife, Dorothy, three daughters and one son.

HARRY R. BAKER, M.D.

Dr. Harry R. Baker, 90, Hayfield physician, died March 26, following a short illness. Born at Wood Lake, Minnesota, he graduated from Hamline Medical School in 1907. Dr. Baker practiced medicine on the Iron Range of the Oliver Mining Company until 1909 when he moved to Waltham, Minnesota. In 1912 he moved to Hayfield where he practiced until his retirement.

He was a member of the American Medical Association, the Zumbro Valley Medical Society, and a 50 Club and Life Member of the Minnesota State Medical Association.

Dr. Baker is survived by his wife, Ella, one son, Dr. Russell L. Baker of Champaign, Illinois, and one daughter, Mrs. Don Gilmer.

ANDREW P. GOBLIRSCH, M.D.

Dr. Andrew P. Goblirsch, 74, Sleepy Eye physician, died February 22. He was born in Wabasso and graduated from the University of Minnesota Medical School.

In 1966, Dr. Goblirsch was honored by the Sleepy Eye Chamber of Commerce for 40 years of service to that community. That same year he was invested as a Knight of St. Gregory, the highest honor that can be bestowed on a layman in the Catholic Church. The appointment was made by Pope Paul VI.

He was a member of the American Medical Association and the Brown County Medical Society and a Life Member of the Minnesota State Medical Association.

Dr. Goblirsch is survived by his wife, Alice, three daughters, Mary Ellen, Judith and Grace. Dr. Albert Goblirsch of Faribault and Dr. Nicholas Goblirsch of Wabasso are his brothers.

DOUGLAS P. HEAD, M.D.

Dr. Douglas P. Head, 74, Minneapolis physician and former professor of medicine at the University of Minnesota Medical School, died April 4. He was the father of Douglas M. Head, former Minneapolis attorney general, and a son of the late Dr. George Douglas Head.

He attended Philips Exeter Academy, Exeter, N.H., and graduated from Yale-Sheffield Scientific Institute in 1922 and from the University of Minnesota Medical School in 1926. He spent 1932 in Vienna in postgraduate study.

Dr. Head retired from the University about five years ago. He was a member of the American Medical Association, the Hennepin Medical Society, the Minnesota Society of Internal Medicine, and a Life Member of the Minnesota State Medical Association.

He is survived by his wife, Ruth, his son, and four daughters, Mrs. Michael Bosanko, Mrs. Douglas Horner, Mrs. Robert Burnett, and Mrs. William Loeffler.

LUVERNE WELLINGTON JOHNSRUD, M.D.

Dr. Luverne Wellington Johnsrud, 62, Hibbing surgeon, died March 11. Born in Mason City, Iowa, he later attended the University of Minnesota Medical School.

He was a former president of the Minnesota Surgical Society and a member of the American Medical Association, the Range Medical Society, and the Minnesota State Medical Association.

Dr. Johnsrud is survived by his wife, Corinne, two sons, Gary and Dr. David Johnsrud, and a daughter, Carol.

Quote: The AMA doesn't represent me. Unquote.

Maybe that's the way you feel. Thinking we do little to protect your way of life. Or that we don't share your views.

If it be true . . .

Who did successfully testify against a headlong rush into a large-scale HMO program?

Who did propose a program of *voluntary* national health insurance and succeeded in enlisting more Congressional co-sponsors for it than any

other national health insurance bill?

Who did propose the development of nationwide community emergency medical services? Who did promote maternal and child care programs? Federal aid to medical schools? Stronger occupational health and safety laws?

The AMA. The fact is, the AMA works hard — and effectively — to represent your interests.

Obviously, we can't represent the views of all physicians all of the time. But the goals we do share far outweigh any differences that may separate us.

Join us.

We can do much more together.

American Medical Association

Book Reviews

BEYOND THE COUCH—Walkenstein, Crown Publishing Company.

Dr. Walkenstein's book **BEYOND THE COUCH** will not endear her to the "medical club," as she puts it, or to psychiatrists in particular. Her opening gambit sets the tone for what follows: "We are living in an age in America where everyone wants to suck a tit and not rough mamas are offering."

Dr. Walkenstein discusses drug abuse as it is practiced by the physician: "Where is the unusual psychiatrist who lets his anxious patient out of his office without tranquilizing pills?" and says further, "There is no tranquilizer that can replace human interaction—on the contrary, it diminishes and limits it." She points out the frustration, anger, and degradation that patients must go through to get medical attention because of the difference of doctors and nurses who show no regard for the dignity of the patient.

She learned early in her internship that doctors perform operations for non-medical, non-health reasons; and states that if the profit motive were removed, there would be a precipitous drop in the number of hysterectomies (or mutilectomies, as she calls them), appendectomies, and tonsillectomies done by surgeons, and in the number of shock therapies administered by psychiatrists.

As one continues to read, the impression becomes a certainty that Dr. Walkenstein is no amateur in the use of pungent and most descriptive four-letter words, both in her writings and with her patients; and even though we are very permissive today in the use of these old Anglo-Saxon four-letter words, there is a barnyard redolence in her writing and in her conversation with her patients. She castigates the medical profession and their belief in the traditional—"Doctors are changeless in rejecting the new and in ostracizing, persecuting, and crucifying anyone in or out of their midst who threatens their additional, secure, boxed-in knowledge; their body of facts that has been taught them, notwithstanding how mad that body lies." She says, with some truth, "When doctors get riled up about quacks and fringy medical people, they somehow seem to protest too much—what is it in themselves they are projecting? The doctor clings to the club for safety . . . the club won't tolerate newly eagles."

Her discussion then centers on the psychiatrist. "Psychiatry in the United States is one big con job and a giant putdown." Dr. Walkenstein goes on to discuss shock therapy, lobotomy, sex education, child raising, marriage, and groups—married and otherwise. In discussing

therapy, she points out that only the personal involvement of the physician cures patients. "No psychiatric tool (technique) ever cured a patient, just as no shovel ever dug a hole." It takes a person to use that tool. "There is no substitute for heart-to-heart, gut-to-gut interaction." The personal touch and contact between doctor and patient is the essence and art of the practice of medicine; and today with the number of patients seeking help, particularly in the psychiatrist's domain, one must have time and more time to develop this kind of rapport which is so necessary to give the patient some kind of relief.

Dr. Walkenstein is brutal in her condemnation of doctors. Her vitriolic condemnation of the majority of physicians is far-fetched and certainly does not include at least 25 percent of our honored profession. This reviewer's impression is that she has unfortunately had contact with "very few decent doctors."

I recommend Dr. Walkenstein's book as well worth reading and thinking about; and if we can be honest with ourselves as physicians and introspective enough, we will begin to see ourselves as she sees us and possibly improve in whatever area of medicine we practice.

Dr. Walkenstein must be given much credit for expressing herself so honestly as to what she has seen and is experiencing in medical practice. Many of her colleagues' voices will be raised in protest, but she will not be drummed out of "the club." She will certainly be sufficiently bruised, however, to earn the Purple Heart.

Milton Abramson, M.D.
Minneapolis, Minnesota

CURRENT DIAGNOSIS & TREATMENT by Marcus A. Krupp and Milton J. Chatton, Lange Medical Publications, Los Altos, California 1973. 996 pp. \$12.00.

The 1973 edition of **Current Diagnosis & Treatment** is out. It covers broad areas of medical practice and is well indexed.

As was indicated in the editor's preface, this book is not intended to be used as a textbook of medicine but to be used as a useful reference book for practicing physicians. The decision to change the publication from annual to biennial seems appropriate since one would not expect enough change in diagnosis and treatment of a given condition to warrant a new edition each year.

It is very handy to have the list of reference articles at the end of each condition. It is well up-dated and this alone may be worth more than the cost of the book.

Classified Advertisements

Classified advertising rates are thirty (30) cents a word; minimum monthly charge \$7.50; key number, fifty (50) cents additional.

Replies to advertisements with key numbers should be mailed in care of Minnesota Medicine, 375 Jackson, St. Paul, Minn. 55101.

ANESTHESIOLOGIST, young Board eligible, FACA, available for two week locum in August, 1973. Terms negotiable. Solo or supervisory. Write MINNESOTA MEDICINE—481, 375 Jackson, St. Paul 55101.

SHELL LAKE CLINIC, LTD., Shell Lake, Wisconsin, expanding to seven man group. Three family physicians and one surgeon desire additional two family physicians and one internist. New 70 bed general hospital adjoins clinic. Excellent remuneration in corporate practice. City surrounds one of largest and finest swimming and fishing lakes in Northwest Wisconsin. Call 715-468-2711 or write to Clinic Manager Darrell Bailey.

GENERAL PRACTITIONER needed as associate in county seat community of 2,000. Modern 35 bed hospital 4 blocks from fully equipped clinic. An excellent opportunity to live the good life in rural Minnesota. Write: Minnesota Medicine-477, 375 Jackson St., St. Paul 55101.

A BETTER PLACE TO PRACTICE MEDICINE.

For those who would prefer to live in a warmer climate, avoid the big city school, traffic and practice problems; contact this multi-specialty group, located in a city of 100,000 people in North Central Texas. Specialists in Internal Medicine, Family Practice, Pediatrics, General and Orthopedic Surgery are needed to complement the current staff of twenty-one full time physicians. Wichita Falls Clinic-Hospital, 1300 Eighth, Wichita Falls, Texas 76301.

ASSOCIATE FOR AAFP member in professional corporation or expense and call sharing association. New clinic building in construction to serve three rural communities. Immediate partnership in corporation, if desired. All corporate benefits immediately. Located in beautiful Hiawatha Valley of southeastern Minnesota, 35 miles from Mayo Clinic and 55 miles from Gunderson Clinic. Contact R. L. Sauer, M.D., Root River Valley Medical Clinic LTD., Box 496, Preston, Minnesota 55965.

PART OR FULL TIME, Southdale or downtown Mpls., GP or internist. Pleasant work, mainly examining executive and professional people, no weekend or evening duty. \$20 per hour part-time or \$30,000 annually full time. Free time easily arranged for outside activities or extra vacations on pro rata income basis. Special arrangements can be made for physical handicaps other than age (62 is the upper limit) or sensory loss. Must be graduate of U.S. school licensed or licensable in Minnesota. Write: MINNESOTA MEDICINE—484, 375 Jackson, St. Paul 55101.

ASSOCIATES WANTED: Family doctors to join growing Family Practice Department in a large multiple specialty medical center, Minneapolis suburb. Excellent opportunity for teaching undergraduate and graduate students in Family Practice. Four man department with excellent growth potential. Reply to Dr. Harley J. Racer, Chairman, Family Practice Department, St. Louis Park Medical Center, St. Louis Park, MN 55416. Telephone 612-927-3320.

WAYZATA MEDICAL BUILDING OFFICE SUITES—

Located in the fastest growing suburban area in the Twin Cities. We offer:

- Surrounding area of lakes, country clubs, woods, beautiful homes;
- Unsurpassed medical building facilities
- Fast growing area—high median family incomes
- Beautiful building—inside and out
- Inner courtyard with trees and landscaping
- Heated indoor parking
- Adjacent access to freeway system
- Low rental rates—favorable base terms
- Financial services

We have grown to fourteen specialties since our building was completed two years ago. We particularly are interested in Orthopedics, Psychiatry, Urology, Otolaryngology, Internal Medicine and Dentistry. Give us a call. We have a lot more to show you and to talk about. Reply to: Mr. Pask, Wayzata Medical Building, 250 North Central Avenue, Wayzata, Minn. 55391, (612) 473-0031.

SOUTHWEST MINN. HEALTH CARE ENTERPRISE—

Six communities working together to recruit physicians to implement model rural health care program designed by and affiliated with University of Minnesota, Dept. of Family Practice. New clinic available, estimated 15,000 in model area. 3 nursing homes, plus other normal attributes of top rural farming area. Contact: Wallace W. Nelson, Lamberton, Minn. 56152. Tele: 507-757-7372.

FAMILY PHYSICIAN needed to replace member (taking F. P. Teaching position) of five man F.P. group in Robbinsdale, suburb of Mpls., Minn. Active family practice includes medicine, pediatrics, surgery, and OB, utilizing two nearby hospitals. Salary one year, full partnership thereafter. Contact D. D. Metz, M.D., 3819 W. Broadway, Mpls., Minn. 55422 (612) 533-2534.

WANTED—Internist—Board qualified or certified for city practice with a group of 2. Good salary. Partnership in future. Write: MINNESOTA MEDICINE—480, 375 Jackson, St. Paul 55101.

Classified Advertisements

P. AUSTIN desires an associate. Partner retiring Florida. \$25,000 salary first year. Partnership after one year. 165 bed hospital. Close to Minneapolis and Rochester. Write: Joseph Mlinar, M.D., 505 N. Main, Austin 55912.

COUNTRY LIVING-METROPOLITAN CONVENIENCE—WANTED AND NEEDED: One or two General Practitioners to set up practice in new and equipped clinic with utilities paid and rent free 6-12 months. Service area of 9,000 and rapidly growing. New hospital in planning stages, new high school under construction. Located within one hour of Minneapolis-St. Paul. Dental, Veterinary, and Mental Health Clinics also located here. Golfing, bowling, fishing, hunting, etc. in area. Interview expenses and all moving expenses paid. Join us for comfortable country living with big city benefits. Try it, you'll like it! Write: MINNESOTA MEDICINE—485, 375 Jackson, St. Paul 55101.

INTERNIST wanted to join Six-man Department in twenty-two man multi-specialty group. Growing incorporated practice; nearly new Clinic facilities; full range of fringe benefits, including profit sharing fund participation and generous time-off allowance; equal shareholder at end of one year; salary first year, incentive pay plan thereafter. City of 35,000 with excellent schools and colleges; fine residential areas for family living; 1½ hours to Twin Cities; much recreational and cultural activity available locally. Great place to live and practice. Call collect or write C. H. Brady, Jr., M.D., Mankato Clinic, Ltd., Mankato, Minn. 56001. (Telephone 507-387-1811).

INTERESTING AND CHALLENGING POSITION AVAILABLE for an energetic family physician. Clinic with six family physicians, one surgeon and one internist, with a smoothly functioning call system, in a rural community close to the Metropolitan area. Please contact B. A. Orr, M.D., Faribault Clinic, 924 N.E. First St., Faribault, Minn. 55021 or phone 1-507-334-3921.

FAMILY PHYSICIANS needed in the community of Tracy, Minn. New clinic being built to accommodate 4 doctors in a clinic setting. Contact Administrator, Tracy Municipal Hospital, Tracy, Minnesota 56175.

GENERAL SURGEON AND INTERNIST needed to join expanding 5-man group. Approximately 4,000 patients per month keeps all extremely busy. Located in the heart of the pines and lakes in growing Northern Minnesota community serving area of 35,000. Community features excellent medical facilities, stable diversified economy, year-round recreation and cultural center, and pleasant family environment. Starting salary \$30,000-plus depending on training and experience, all fringes including IRS-approved pension plan. We invite you to call or write us for more information. K. H. Stolen, M.D. or T. R. Brill, Administrator, Box L, Grand Rapids, Minnesota 55744: or call 218-326-6613 (day) or 218-326-5447 (evenings).

FAMILY PRACTITIONER WANTED to join small progressive group serving beautiful Mille Lacs Lake area, only eighty miles north of Minneapolis. Modern clinic and JCAH seventy-three bed hospital and ECF. Excellent income potential; group support, two out of three weekends off. Away from the madding crowd; yet not too far away. Good schools; clean, uncrowded environment; lakes to live on; unfettered living. We need you. Contact: Dr. Dennis R. Jacobson, 612-532-3113 (clinic), 612-532-3628 (home), or Marshall E. Engstrom, Hospital Administrator, 612-532-3154 (office), 612-532-3693 (home).

G.P. OR INTERNIST. 40 hour week, no night calls, mainly examining executive and professional people. Easily arranged vacation time or time for varied pursuits. Must be 60 or below, but special provision can be made for orthopedic, cardiac or respiratory impairments. \$30,000 base. Write MINNESOTA MEDICINE—479, 375 Jackson, St. Paul 55101.

OB-GYN or General Practitioner wanted. Seven-man clinic in growing northern Minnesota community with diversified economy, good schools and recreational area. Write: John Nesseth, Administration, Grand Rapids Clinic, Grand Rapids 55744.

EQUIPMENT FOR SALE: 300 MA X-ray, Shield. Pediatric table/scale, Steeline Exam Table, Sterilizer Cabinet, Specialist's Cabinets, suction pressure unit, Operator's Stools, Diapulse, Microthermy, Diathermy, Unimeter, Dictaphone, Coreco camera. Excellent condition. Reasonable. H. C. Winge, M.D., 221 Rice Creek Terrace, Fridley, MN 55432, (612) 566-8202.

T₄ IS THE PREDICTABLE HORMONE BECAUSE IT LOVES PROTEIN.

ALL THYROID-FUNCTION TESTS ARE USEFUL IN MONITORING SYNTHROID THERAPY

TWO GOOD REASONS WHY THE ROAD TO NORMALIZED THYROID STATUS IS SO SMOOTH FOR THE SYNTHROID PATIENT

SYNTHROID® (sodium levothyroxine) is pure synthetic T₄, the major circulating thyroid hormone. It is reliable to use because of its affinity for protein-binding sites in the blood. T₃ is more fickle. Sometimes it binds. Sometimes it doesn't. T₄ more *predictably* binds to protein.

No calculations are needed, test interpretation is simple.

Any of the commonly used T₄ thyroid function tests (P.B.I., T₄ By Column, Murphy-Pattee, Free Thyroxine) are useful in monitoring patients on T₄ because they *all* measure T₄. Patients on SYNTHROID are thereby easy to monitor because their results will fall within predictable, elevated test ranges. Of course, clinical assessment is the best criterion of the thyroid status of the drug-treated patient.

(1) The onset of action of T₄ is gradual. It has a long in vivo "half-life" of over six days. (Occasional missed doses or accidental double-doses are of concern because of this fact.) (2) Since SYNTHROID contains only T₄, the potential for metabolic surges traceable to more potent iodides (T₃) is eliminated.

TEST	HYPOTHYROID	SYNTHROID THERAPEUTIC NORMAL
P.B.I.	Less than 4 mcg %	6-10 mcg %
T ₄ By Column	Less than 3 mcg %	7-9 mcg %
T ₃ (Resin)	Less than 25%	27-35%
T ₃ (Red Cell)	Less than 11%	11.5-18%
Free Thyroxine	Less than 0.7 nanograms %	0.7-2.5 nanograms %
Murphy-Pattee	Less than 2.9 mcg %	4-11 mcg %

AS WITH ANY THYROID PREPARATION, CAUTIOUS OBSERVATION OF THE PATIENT DURING THE BEGINNING OF THERAPY WILL ALERT THE PHYSICIAN TO ANY UNTOWARD EFFECTS.

Side effects, when they do occur, are related to excessive dosing. Caution should be exercised in administering the drug to patients with cardiovascular disease. See the accompanying prescribing information for additional details. Write Flint Laboratories.

t. Their thyroid status is
led on SYNTHROID alone,
e presence of T_3 in these
has been clearly shown.

WHY DOES SYNTHROID COST LESS THAN SYNTHETIC DRUGS CONTAINING T_3 ?

Very simple. T_3 costs more to make synthetically than does T_4 . So it is economically necessary for a synthetic thyroid medication containing T_3 to cost more than one containing T_4 alone. Synthetic combinations cost patients nearly 50% more than SYNTHROID³ because the T_3 costs more to start with; also there is the additional expense of formulating a tablet containing two active ingredients.

City _____

State _____

Zip _____

Indications: SYNTHROID (sodium levothyroxine) is specific replacement therapy for diminished or absent thyroid function resulting from primary or secondary atrophy of the gland, congenital defect, surgery, excessive radiation, or antithyroid drugs. Indications for SYNTHROID (sodium levothyroxine) Tablets include myxedema, hypothyroidism without myxedema, hypothyroidism in pregnancy, pediatric and geriatric hypothyroidism, hypopituitary hypothyroidism, simple (nontoxic) goiter, and reproductive disorders associated with hypothyroidism. SYNTHROID (sodium levothyroxine) for Injection is indicated for intravenous use in myxedematous coma and other thyroid dysfunctions where rapid replacement of the hormone is required. The injection is also indicated for intramuscular use in cases where the oral route is suspect or contraindicated due to existing conditions or to absorption defects, and when a rapid onset of effect is not desired.

Precautions: As with other thyroid preparations, an overdosage may cause diarrhea or cramps, nervousness, tremors, tachycardia, vomiting and continued weight loss. These effects may begin after four or five days or may not become apparent for one to three weeks. Patients receiving the drug should be observed closely for signs of thyrotoxicosis. If indications of overdosage appear, discontinue medication for 2-6 days, then resume at a lower dosage level. In patients with diabetes mellitus, careful observations should be made for changes in insulin or other antidiabetic drug dosage requirements. If hypothyroidism is accompanied by adrenal insufficiency, as Addison's Disease (chronic subcortical insufficiency), Simmonds's Disease (panhypopituitarism) or Cushing's syndrome (hyperadrenalism), these dysfunctions must be corrected prior to and during SYNTHROID (sodium levothyroxine) administration. The drug should be administered with caution to patients with cardiovascular disease; development of chest pains or other aggravations of cardiovascular disease requires a reduction in dosage.

Contraindications: Thyrotoxicosis, acute myocardial infarction. **Side effects:** The effects of SYNTHROID (sodium levothyroxine) therapy are slow in being manifested. Side effects, when they do occur, are secondary to increased rates of body metabolism; sweating, heart palpitations with or without pain, leg cramps, and weight loss. Diarrhea, vomiting, and nervousness have also been observed. Myxedematous patients with heart disease have died from abrupt increases in dosage of thyroid drugs. Careful observation of the patient during the beginning of any thyroid therapy will alert the physician to any untoward effects.

In most cases with side effects, a reduction of dosage followed by a more gradual adjustment upward will result in a more accurate indication of the patient's dosage requirements without the appearance of side effects.

Dosage and Administration: The activity of a 0.1 mg. SYNTHROID (sodium levothyroxine) TABLET is equivalent to approximately one grain thyroid, U.S.P. Administer SYNTHROID tablets as a single daily dose, preferably after breakfast. In hypothyroidism without myxedema, the usual initial adult dose is 0.1 mg. daily, and may be increased by 0.1 mg. every 30 days until proper metabolic balance is attained. Clinical evaluation should be made monthly and PBI measurements about every 90 days. Final maintenance dosage will usually range from 0.2-0.4 mg. daily. In adult myxedema, starting dose should be 0.025 mg. daily. The dose may be increased to 0.05 mg. after two weeks and to 0.1 mg. at the end of a second two weeks. The daily dose may be further increased at two-month intervals by 0.1 mg. until the optimum maintenance dose is reached (0.1-1.0 mg. daily).

Supplied: Tablets: 0.025 mg., 0.05 mg., 0.1 mg., 0.15 mg., 0.2 mg., 0.3 mg., 0.5 mg., scored and color-coded, in bottles of 100, 500, and 1000. Injection: 500 mcg. lyophilized active ingredient and 10 mg. of Mannitol, N.F., in 10 ml. single-dose vial, with 5 ml. vial of Sodium Chloride Injection, U.S.P., as a diluent. SYNTHROID (sodium levothyroxine) for Injection may be administered intravenously utilizing 200-400 mcg. of a solution containing 100 mcg. per ml. If significant improvement is not shown the following day, a repeat injection of 100-200 mcg. may be given.

denise Day

David J. Dunlap, M.D.

JULY, 197

Everybody experiences psychic tension.

Most people can handle this tension.

Some people develop excessive psychic tension and need your counseling,

and a few may need counseling
and the psychotropic action of Valium® (diazepam).

Before deciding to make Valium (diazepam) part of your treatment plan, check on whether or not the patient is presently taking drugs and if so, what his response has been to them. Along with the medical and psychiatric history, this information can help you determine initial dosage, the possibility of side effects and the ultimate prospects of success or failure.

While Valium can be a most helpful adjunct to your counseling, it should be prescribed only as long as excessive psychic tension persists and should be discontinued when you decide it has accomplished its therapeutic task. In general, when dosage guidelines are followed, Valium is well tolerated (see Dosage). For convenience it is available in 2-mg, 5-mg and 10-mg tablets.

Drowsiness, fatigue and ataxia have been the most commonly reported side effects.

Until response is determined, patients receiving Valium should be cautioned against engaging in hazardous occupations requiring complete mental alertness, such as driving or operating machinery.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect.

Adults: Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. **Geriatric or debilitated patients:** 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) **Children:** 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

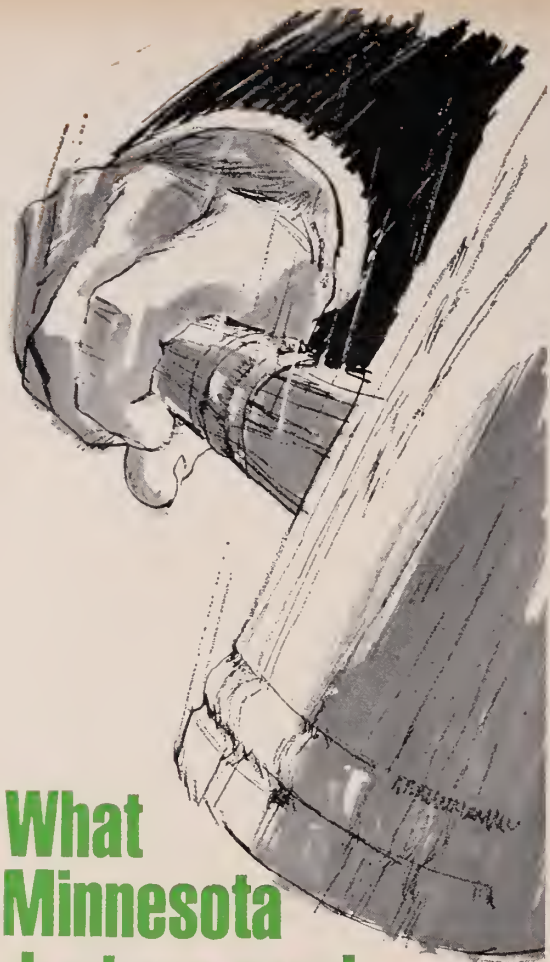

Supplied: Valium® (diazepam) Tablets, 2 mg, 5 mg and 10 mg; bottles of 100 and 500. All strengths also available in Tel-E-Dose® packages of 1000.

The diabetic
who has
too much...

too much sugar,
too much fat.

Maybe the last thing she needs is more of her own insulin. Especially when you consider that many overweight diabetics already have normal or high levels of endogenous insulin and that insulin is lipogenic.

If she just won't diet and oral therapy is indicated in adult-onset, nonketotic diabetes...

DBI-TD® Geigy
phenformin HCl

lowers blood sugar without raising
blood insulin.

For complete details, including dosage,
please read the prescribing information.
It's summarized below.

phenformin HCl
of 25 mg.
phenformin HCl
Disintegration
les of 50 and 100 mg.

Indications: Stable adult diabetes mellitus; sulfonamide failures, primary and secondary; adjunct to therapy of unstable diabetes mellitus.
Contraindications: Diabetes mellitus that can be controlled by diet alone; juvenile diabetes mellitus; uncomplicated and well regulated on insulin; acute complications of diabetes mellitus (diabetic acidosis, coma, infection, gangrene); or immediately after surgery where insulin is indispensable; severe hepatic disease; renal dis- with uremia; cardiovascular collapse (shock); disease states associated with hypoxemia.
Precautions: Use during pregnancy is to be avoided.
Warnings: 1. *Starvation Ketosis:* This must be differentiated from "insulin lack" ketosis and is characterized by ketonuria which, in spite of rel-

atively normal blood and urine sugar, may result from excessive phenformin therapy, excessive insulin reduction, or insufficient carbohydrate intake. Adjust insulin dosage, lower phenformin dosage, or supply carbohydrates to alleviate this state. Do not give insulin without first checking blood and urine sugar.

2. *Lactic Acidosis:* This drug is not recommended in the presence of azotemia or in any clinical situation that predisposes to sustained hypotension that could lead to lactic acidosis. To differentiate lactic acidosis from ketoacidosis, periodic determinations of ketones in the blood and urine should be made in diabetics previously stabilized on phenformin, or phenformin and insulin, who have become unstable. If electrolyte imbalance is suspected, periodic determinations should also be made of electrolytes, pH, and the lactate-pyruvate ratio. The drug should be withdrawn and insulin, when required, and other corrective measures instituted immediately upon the appearance of any metabolic acidosis.

3. *Hypoglycemia:* Although hypoglycemic reactions are rare when phenformin is used alone, every precaution should be observed during the dosage adjustment period particularly when insulin or a sulfonylurea has been given in combination with phenformin.

Adverse Reactions: Principally gastrointestinal; unpleasant metallic taste, continuing to anorexia, nausea and, less frequently, vomiting and diarrhea. Reduce dosage at first sign of these symptoms. In case of vomiting, the drug should be immediately withdrawn. Although rare, urticaria has been reported, as have gastrointestinal symptoms such as anorexia, nausea and vomiting following excessive alcohol intake. (B) 98-146-103-E (6/72)

For complete details, including dosage, please see full prescribing information.

GEIGY Pharmaceuticals
Division of CIBA-GEIGY Corporation
Ardley, New York 10502

What should a medication for sleep be expected to provide?

Before prescribing Dalmane (flurazepam HCl), please consult Complete Product Information, a summary of which follows:

Indications: Effective in all types of insomnia characterized by difficulty in falling asleep, frequent nocturnal awakenings and/or early morning awakening; in patients with recurring insomnia or poor sleeping habits; and in acute or chronic medical situations requiring restful sleep. Since insomnia is often transient and intermittent, prolonged administration is generally not necessary or

recommended.

Contraindications: Known hypersensitivity to flurazepam HCl.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness (e.g., operating machinery, driving). Use in women who are or may become pregnant only when potential benefits have been weighed against possible hazards. Not recommended for use in persons under 15 years

of age. Though physical and psychological dependence have not been reported at recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage.

Precautions: In elderly and debilitated patients, initial dosage should be limited to 15 mg to preclude oversedation, dizziness, or ataxia. If combined with other CNS-depressant drugs, consider potential additive effects. Employ usual precautions in patients who are severely depressed, or who

for 7 to 8 hours without need to repeat dosage during the night

No sleep medication has been as rigorously evaluated in the sleep research laboratory as Dalmane. Insomnia patients given one 30-mg capsule of Dalmane at bedtime, on average: fell asleep within 17 minutes, had fewer nighttime awakenings, spent less time awake after sleep onset, and slept for 7 to 8 hours with no need to repeat dosage during the night.

with consistency

Dalmane has been shown to be consistently effective even during consecutive nights of administration. Thus there is little likelihood for the need to increase dosage to maintain therapeutic effect.

Dalmane (flurazepam HCl) is a distinctive sleep medication—a benzodiazepine specifically indicated for insomnia. It is not a barbiturate or methaqualone, nor is it related chemically to any other available hypnotic.

with relative safety

Chronic tolerance studies have confirmed the relative safety of Dalmane; no depression of cardiac or respiratory function was noted in patients administered recommended or higher doses for as long as 90 consecutive nights. Dalmane is generally well tolerated and morning "hang-over" is relatively infrequent. Dizziness, drowsiness, lightheadedness and the like have been the side effects noted most frequently, particularly in elderly and debilitated patients. (An initial dose of Dalmane 15 mg should be prescribed for these patients.)

DALMANE[®]

(flurazepam HCl)

When restful sleep is indicated

One 30-mg capsule h.s.—usual adult dosage
(15 mg may suffice in some patients).

One 15-mg capsule h.s.—initial dosage for elderly or debilitated patients.

ROCHE

ROCHE LABORATORIES
Division of Hoffmann-La Roche Inc.
Nutley, New Jersey 07110

pression or suicidal tendencies. Blood counts and liver and kidney tests are advised during therapy. Observe usual precautions of impaired renal or function.

Reactions: Dizziness, drowsiness, lightheadedness, staggering, ataxia have occurred, particularly in debilitated patients. Severe lethargy, disorientation and possibly indicative of drug intolerance, have been reported.

Also reported were headache, heartburn, upset stomach, nausea, vomiting, diarrhea, constipation, GI pain, nervousness, talkativeness, apprehension, irritability, weakness, palpitations, chest pains, body and joint pains and GU complaints. There have also been rare occurrences of sweating, flushes, difficulty in focusing, blurred vision, burning eyes, faintness, hypotension, shortness of breath, pruritus, skin rash, dry mouth, bitter taste, excessive salivation, anorexia, euphoria, depression, slurred speech,

confusion, restlessness, hallucinations; and elevated SGOT, SGPT, total and direct bilirubins and alkaline phosphatase. Paradoxical reactions, e.g., excitement, stimulation and hyperactivity, have also been reported in rare instances.

Dosage: Individualize for maximum beneficial effect. **Adults:** 30 mg usual dosage; 15 mg may suffice in some patients.

Elderly or debilitated patients: 15 mg initially until response is determined.

Supplied: Capsules containing 15 mg or 30 mg flurazepam HCl.

Opinion & Dialogue

"Prescription drugs – who should determine the maker?"

Manufacturers
Association

"Too many doctors are indifferent to the economic consequences of their decisions." So stated a reader of *Medical News Report* (December 4, 1972), an independent weekly newsletter published by AMA Chief Executive F. J. L. B. game, M.D.

Doctor, are you indifferent...?

In discussing an anticipated increase in Blue Shield rates, Dr. Ingame's newsletter had this to say:

"In general, it can be said that we have given the impression that we are not particularly concerned with the increase in cost of health care for patients..."

"True, an MD's training is primarily scientific, but in the real world of practice, all of his scientific decisions have a price tag, or an economic impact. The economics of health care beckon the practitioner's attention. Concern for economics of medicine..."

When the pharmacist recommends that a drug product other than the one ordered be dispensed, the prescriber invariably permits the change when he feels the best interests of the patient will be served.

Shortcomings of Pro-Substitution Argument

The fact remains that it is essential for the prescriber to know when the change is being contemplated, and to be in a position to consent or demur. Without that opportunity, the unilateral decision of the pharmacist made in the absence of clinical judgment on the part of the physician, on the edge of the patient, could expose the patient to needless risks, and in addition, jeopardize the relationship between the professions of Pharmacy and Medicine. In my view, there is no offset in the pro-substitution argument that offsets these risks.

The Issue of Drug Knowledge

Substitution advocates claim that the primary justification for changing the rules is the desire to better utilize pharmacists' knowledge about drugs. Yet the pharmacist's task to keep current on the entire field of drug therapy, to some extent, puts him at a disadvantage. More often, a practicing physician with his expert knowledge of no more than

should be an obligation of medical practice...

"Medical societies ought to continue campaigns to point out the substantial savings that could be realized thru deductible insurance protection for catastrophic illnesses. At the very least, they should, in the patients' interest, question the policies of any insurance organization that raises health care costs by forcing policyholders to buy insurance they may not need or want and probably won't ever use.

"Too many doctors are indifferent to the economic consequences of their decisions. Too many, for example, habitually hospitalize patients for the convenience of the MD. It's no sense to deny such habits exist...

"Doctors, thru their medical societies, have unhesitatingly appealed to their patients for support in the fight against government interference with the private practice of medicine. At the public in the past has responded. It's time the American Medical Association and state and local medical societies paid off the debt by decisive action to hold down the cost of medical care."

Cost of Drugs

Insurance rates and hospital charges are only two factors in health

care. Drugs that he selects to treat the majority of conditions encountered in his practice. Moreover, the physician's choice of a specific brand is based on his knowledge of the patient's medical history and current condition, and his experiences with a particular manufacturer's product.

Some substitution proponents have argued that the dispensing of a prescription is a simple two-party transaction between the pharmacist and the patient, and that a substituting pharmacist may avoid even a technical breach of contract by simply notifying the patient that he is making a substitution. I would judge that the courts would be sympathetic toward a pharmacist who substituted without physician approval and who undertook a legal defense that seeks to make the patient responsible for the pharmacist's actions.

Reduced Prescription Prices?

Substitution advocates are suggesting to the consumer, and particularly the consumer activist, that reduced prescription prices could justify legalization of substitution. I have seen absolutely no evidence to justify this claim. To the contrary, experience in Alberta, Canada, where substitution is authorized, suggests

care costs. The cost of drugs—both prescription and nonprescription—is another.

And when it comes to drug costs, the nation's pharmacists are concerned. Through their national professional society, the American Pharmaceutical Association, pharmacists are advising the public to use nonprescription medication cautiously and conservatively, and to seek the advice of their pharmacist before selecting or purchasing such drugs.

Outdated Laws

The pharmacist also is aware that when it comes to prescription drugs, often he has an even greater opportunity to reduce the cost to the patient—with no sacrifice in the quality of the medication dispensed. But in many states, outdated and antiquated laws prevent the pharmacist from engaging in drug product selection. "Drug product selection" simply means that the pharmacist functions in the patient's interest by consciously choosing, from the multiple brands available, a low-cost quality brand of the specific drug to be dispensed in response to the physician's prescription order.

Much *misinformation* has been purposely spread by those who stand to gain financially by maintaining

high drug costs to the public. An endless stream of propaganda has emanated from the drug industry in an effort to persuade the medical profession that these so-called anti-substitution laws should be retained. And as long as these laws are retained, the drug industry will continue its current marketing practices which contribute unnecessarily to high drug costs to patients. These practices also are inviting government agencies to expand their restrictive controls on physicians and pharmacists.

APhA Efforts

As pharmacists, we are concerned about health care costs. We hope that every physician shares our concern on this vital issue, and will give his personal support to the constructive efforts APhA has undertaken in the interest of all patients.

(For a complete discussion of drug product selection, you are invited to request a free copy of the "White Paper on the Pharmacist's Role in Product Selection" from: American Pharmaceutical Association, 2215 Constitution Avenue, N.W., Washington, D.C. 20037.)

the opposite.

Many pharmacists understandably are concerned about the cost of maintaining multiple stocks of similar products. While there is no doubt that inventory costs rise when additional brands are stocked, it would be interesting to know how much they rise, and how many pharmacists actually stock *all* brands—of, say, ampicillin or tetracycline—or how long they keep "slow moving" products on their shelves before they are returned for credit. To ask that the industry eliminate multiple sources is to ask competitors to stop competing.

Drug Substitution—A License for the Unethical

Anti-substitution repeal would favor "corner cutting" pharmacists and manufacturers. For them, free substitution would be not a right, but a license. As an aftermath, it is quite likely that the confidence of both physicians and patients in the profession of Pharmacy would be eroded, as revelations about the unconscionable behavior of an undisciplined few were magnified in the press or in professional circles.

Summary

In short, what the American Pharmaceutical Association advo-

cates as a broad-spectrum panacea looks to us to be not only a minority view (advocacy of substitution is by no means a uniform policy in Pharmacy), but also an extraordinarily costly and ineffective remedy, whose side effects are odious. We believe (1) that an impressive majority of pharmacists prefer to work with Medicine and with industry, for the consumer, and for the general good, (2) that they seek the privilege to substitute when the patient might gain and when the patient's doctor agrees, and (3) that they seek to work for the resolution of genuine grievances openly and professionally.

DIRECTOR of MENTAL HEALTH

We are seeking a psychiatrist to direct the Milwaukee County Mental Health Center, a comprehensive community mental health center, organized into six catchment area programs including out-reach stations located within the community. 1,000 acute and long-term psychiatric beds; an ultra modern day hospital; and, a soon to be completed 180 bed inpatient resident and day care treatment center for children and adolescents. The Center is a principal psychiatric teaching resource for the Medical College of Wisconsin and has training programs for interns, residents, nurses and other students.

Requires Wisconsin licensure or eligibility for same and at least 5 years comprehensive experience as a mental health director, educator, or administrator preferably in an accredited mental health program, university or hospital.

This is a timely opportunity since we can offer the person appointed to this position the chance to make several critical appointments to new subordinate positions. Excellent employee fringe benefit program and salary. Send vita to:

Edwin A. Mundy, Director
Institutions & Departments

President's Letter

THERE IS IN our land a strange unwillingness among some to look and act like what they are. Boys wear long hair and high heels while girls have abandoned cosmetics and frills and taken to denims and boots. Some of this is good for there is no doubt there has been discrimination—at times on the basis of race—at times, religion—at times, sex. Some, however, is merely confusing. The traditional specialization of effort whether based on sex or training or ability has contributed much to man's ability to modify his environment and to make progress.

In our field some of this role confusion also rears its head. Many of us remember certain identifying symbols among hospital people. In those long ago days you could tell a doctor by the coat he wore and possibly by the stethoscope he carried. He was white, starched stiff and usually impeccable although an occasional less compulsive brother might show up in a frayed and even soiled version of white coat. There was a sort of hierarchical designation which started role and function. It was not necessary to buy a program to tell the players.

Gradually the whole thing eroded. All sorts of others began to take on the garb and appearance and even to strive for the duties of what was considered high man on that particular totem pole. The hallowed symbols of physicianship dis-

solved into a sea of anonymity which threatens to engulf our profession.

While this is something of a *reductio ad absurdum*, nonetheless it must be recognized that there are many who resent the pyramid—the image—the power to practice medicine—who continue to espouse the notion that we should all meld into what is known as the “health care team.” There is even some belief that decisions should be made in consort rather than by the only person with the legal and ethical base, as well as the training, to make fundamental medical decisions.

In the proposed system we shall wallow around in a puddle of indecisiveness while the health care team carries out its infinite debate and permits our patients to flounder and wonder, or we can exercise our ancient but still modern function and give leadership where it is so badly needed. In all this mass of alikeness the physician can still be distinguished—not by white coat—not by dangling stethoscope, but rather by his concerned look—his sometime fatigue and his willingness to abjure the 40 hour week—to accept the personal rather than institutional responsibility and to be what he is 24 hours a day while others abandon their role in search of some holy grail. Harry Truman pungently described where the buck stops in the political system. Doctors have always known where the buck stops in the medical system.

A handwritten signature in cursive script that reads "John J. Regan".

President
Minnesota State Medical Association

In Appreciation

It is a sincere pleasure to act as spokesman for the many members of the Minnesota State Medical Association who attended the exciting 1973 Annual Meeting in expressing our deep appreciation to the firms listed below who participated in our Annual Meeting exhibit. The exhibits were tasteful and informative and contributed significantly to the overall quality of this meeting. To each of these firms, I wish to express my personal thanks and I urge each member to acknowledge their participation when visiting with representatives of these firms.

Chemonucleolysis

ROBERT A. WENGLER, M.D.*

CHEMONUCLEOLYSIS IS THE enzymatic curettage of the nucleus pulposus of the intervertebral disc. After 10 years of clinical trial in man it appears that the procedure has merit as a primary definitive measure in the treatment of lumbar disc syndrome. Investigators presented their findings in a symposium at the annual meeting of the American Academy of Orthopedic Surgeons this past February.

The commonly accepted explanation of the pathogenesis of the disc syndrome is that of compression of a nerve root by a bulging or a protrusion of the annulus fibrosis and/or nucleus pulposus of the intervertebral disc. The validity of this thesis is challenged by the observation that pressure alone on a peripheral nerve gives rise to paresthesias, not pain, as evidenced by pressure on the ulnar or the tibial nerves. Macnab¹ reports a study of 12 patients with herniated discs in which, at the time of surgery, Fogarty catheters placed in the foramina of the involved nerve roots as well as in the foramina of normal roots, either above or below the level of pathology. Distention of the catheters postoperatively produced dysesthesias along the distribution of the "normal" roots while it produced sciatic pain in the roots previously compressed by a disc herniation. These observations suggest that nerve root pressure is not the sole cause of pain experienced in disc herniation and that in all probability there is some chemical mediation of pain.

In the early 1950's the concept that enzymes might transform the interior of discs into fibrous tissue was proposed. The feasibility of enzymatic therapy was summarized by Hirsch in 1959 and later by Mitchell. In 1963 Lyman Smith et al. injected chymopapain into discs of experimental animals and subsequently initiated a clinical trial in man.^{2,3} Their hypothesis was that enzymatic removal of the central contents of the disc would produce relief of symptoms.

Chymopapain is a proteolytic enzyme which is extracted from the fruit of the *Carica papaya*, a palm like tree. Its primary action on the central

contents of a disc is that of hydrolysis and dissolution of the non-collagenous protein which interconnects long-chain mucopolysaccharides. The initiating events in prolapse of a disc are felt to involve partial depolymerization of these long-chain mucopolysaccharides.⁴ One consideration is that nuclear chondromucoprotein depolymerizes slowly in the normal course of aging and erratically in the case of disc prolapse. Clinical healing is thought to occur when the chondromucoprotein is thoroughly degraded. Chymopapain rapidly converts these long-chain molecules into soluble metabolites (keratosulfate, chondroitin sulfate and protein), and relieves the discs of their undesirable effects, be they chemical, mechanical or whatever.⁵ (Macnab reported a series of 10 patients in which the appearance of myelographic defects was unchanged following clinically successful chemonucleolysis.) More complex modes of action have been postulated and the above comments are probably, at best, an oversimplification. Nevertheless, the central contents of the disc are converted into a dense rubbery mass and the disc is, in effect, "decompressed."

The introduction of the chymopapain into the disc is usually done under general anesthesia and under fluoroscopic control. A lateral approach to the disc through the paraspinal muscle masses with a six to eight inch spinal needle is recommended. The point of introduction is approximately 8.0 cm. lateral to the posterior spine and at about a 45° angle to the sagittal plane. Trans-thecal approach to the disc is avoided for reasons which will be discussed later, but the approach may be used if lateral introduction is technically impossible. Selection of the disc to be injected is based generally on the same criteria as for surgical excision: clinical localization, myelography, and discography. Myelography is done as an independent procedure. Discography is done at the time of the chemonucleolysis.⁶

Therapeutic results appear to parallel those of operative intervention with perhaps a slight edge afforded to the chemos. The most impressive benefits are obtained in those patients who would

*Minneapolis, Minnesota.

be considered as ideal candidates for laminectomy, i.e., those with relatively short history of severe sciatic pain, with evidence of marked unremitting root tension, with significant defect on myelography, and/or reproduction of clinically experienced pain on discography. As with surgery, benefits reach diminishing returns in patients with long standing disease, "complicated" disc herniation, spinal stenosis, poorly defined lesions and previous operative manipulation.

The action of the enzyme is immediate. Aspiration of the disc within minutes following an injection yields a cloudy precipitate consisting of the end products of the degraded substrate.⁷ Approximately one-third of the patients reportedly obtain dramatic relief of pain immediately following the injection. In the majority of those realizing symptomatic relief the leg pain subsides within 48 hours. The post-injection course is characterized by back pain and muscle spasms for a period of several days. Observers report the pain appears to be similar to that of a disc space infection. These symptoms are self-limiting and the patient is usually discharged from the hospital after an average stay of five to six days.

In 1969 Smith² reported the first 150 patients so treated with follow-up periods of six to 60 months. Eighty-three percent of this series had complete relief of backache and sciatica with no residual incapacity. Seven percent had incomplete relief of pain but no incapacity for work, and 10 percent had no improvement. These figures included patients treated who had had previous spinal surgery. Eighty-eight percent of the patients with virgin backs reportedly had complete relief. Physicians from various centers reported to the Academy symposium their experience with the drug in over 2500 cases. Their results were generally comparable to those reported by Smith but with some variations for the different type of problem treated. The presence of symptoms of long duration, symptoms consisting predominantly of back pain and of little or no sciatica, history of previous back surgery, obesity and emotional disturbances militated against a successful outcome.

Adverse reactions to the drug have been observed. The main hazard in its clinical use is that of anaphylactoid response. One death has been reported although it was not known for certain if it occurred in response to the enzyme or to contrast used in the discography. Lesser sensitive reactions have also been reported. The surgeon and the anesthesiologist in attendance must be alert to this possibility. (A history of sensitivity to Adolph's Meat Tenderizer is a contraindication to its use.)

Toxicologic studies of the drug have shown that in large doses it breaks down the cement bond between the endothelial cells of the capillaries giving rise to massive hemorrhage. The small vessels of the arachnoid are particularly susceptible to the action of chymopapain and if given intrathecally into experimental animals in low dose produces subarachnoid hemorrhage. It is for this reason that the posterior transthecal approach to the disc is avoided. Accidental intrathecal injection would be fraught with hazard. Epidural and intradiscal injections of the drug in doses up to 1,000 greater than the effective therapeutic dose are well tolerated in experimental animals.

The official status of chymopapain at the present time is that of an experimental drug, it can only be administered with a permit from the FDA. Apparently permits in addition to those already granted are not forthcoming. Proponents of the procedure are hopeful that the drug will be released for general use in the near future.

Chemonucleolysis is a major innovation in the surgical treatment of lumbar disc disease. The word "surgical" is purposely chosen to emphasize that this is not an alternative to accepted conservative management. The temptation of overutilization of the drug when released will be considerable. The present indications for its use are in patients who have failed to respond to conservative management and who are symptomatic to the degree that surgery is indicated. The procedure will not supplant laminectomy. Patients who fail to respond to the chemonucleolysis are generally considered as candidates for further definitive surgery.

Oral Care in Radiation Therapy

DAVID J. BROUDE, D.D.S.*; DANIEL E. WAITE, D.D.S., M.S.† AND
SEYMOUR H. LEVITT, M.D.‡

ABOUT 12 PERCENT of all cancers occur in the head and neck regions.¹ Treatment involves surgery, radiation, or a combination of surgery and radiation, and chemotherapy. Maintenance of acceptable oral health in patients receiving radiation is the subject of this paper.

Stafne reports three major oral problems which can be associated with concentrated doses of radiation to the facial area:² interference with normal development of the teeth and jaws, rampant caries, and osteoradionecrosis.² The mechanics which bring about these pathological changes are not well understood. However, many investigators feel that the basis is injury occurring at the single cell level.³

Radiation Therapy

The incidence of complications following radiation therapy appears to be decreasing due to modification of radiologic techniques and the use of supervoltage therapy.

Multiple and small portals for the radiation have been adapted.⁴ A technique of radiation administration delivering cancericidal doses of 5000 to 7000 rads to a tumor usually involves a daily dose of 150 to 200 rads four or five times per week.

The advantages that the supervoltage therapy has over the use of low and medium energy radiations are its bone sparing and tissue sparing effects. Some now believe that 1000 rads per week using megavoltage radiation will generally not cause any major complications if the total dose does not exceed 5000 rads.⁵ According to Erickson, however, the incidence of osteoradionecrosis increases in direct proportion to a radiation absorbed dose above 4000 rads.⁶

Oral Care Before Radiation

Before radiation therapy has begun, the patient

should be seen by a dentist if either the oral cavity or the salivary glands are part of the field. A careful oral examination should be carried out including roentgenographic examination, thorough soft tissue examination via palpation, examination of the teeth, and evaluation of the periodontium.¹ Calculus, plaque, and stains should be thoroughly removed. The patient should be instructed in the details of oral hygiene. A brushing technique must be taught that will be effective, consistent, and thorough. Many periodontists recommend one in which the brush is held into the marginal gingival area and a circular motion is used. A soft brush and non-abrasive toothpaste are recommended. Restorations should be of the highest quality with no sharp margins. A fixed prosthesis is preferred to a removable one.

Fluoride treatments to the teeth should be given daily during and following radiation (Figure 1). Fluoride application involves the use of individual plastic tooth covers constructed for each arch or the construction of custom made mouth guards. Before each application a 1% solution of viscous sodium fluoride is placed in the carrier and delivered to each arch for five minutes (Figure 2). After removal, the patient is instructed to not

Fig. 1—Intra-oral photo demonstrating good oral hygiene throughout radiation therapy of oral tissues.

*Dental Fellow, University of Minnesota, School of Dentistry.

†Professor and Chairman, Division of Oral Surgery, University of Minnesota, School of Dentistry.

‡Professor and Head, Department of Therapeutic Radiology, University of Minnesota Hospitals.

rinse for approximately half an hour. Daily applications can be done at home and should be carried out indefinitely. Whether teeth are present or not, warm oral lavage should be carried out during and after the period of radiation. One teaspoonful of baking soda and one-half teaspoonful of

salt are added to one quart of luke-warm water. The patient should be encouraged to use this oral rinse three to five times daily and more frequently if the mouth is dry.

A decision for removal of teeth should be based on extensive caries, periodontal involvement, lack of opposing teeth, partial impaction or incomplete eruption, periapical lesions, and oral hygiene status of the patient.⁸ Endodontics may be employed to retain specific teeth for esthetic or prosthetic needs. Some clinicians use the guideline that any tooth that may have to be removed during the subsequent 12 month period should be extracted prior to radiation. Carious or periodontally involved teeth directly in the line of radiation should be extracted. Alveolectomies should be performed when indicated, and sufficient bone may have to be removed to permit a careful soft tissue closure which will avoid delayed healing. As the irradiated bone is slow to remodel, meticulous surgery is necessary. Tori should be left unless they are sharp or their removal is indicated for prosthetic reasons. Particular attention should be given to the mylohyoid ridge area. Deeply impacted teeth covered by bone and soft tissue may be left as the bone will not resorb if it is irradiated and a postoperative osteitis may delay the initiation of the radiation therapy. Partially erupted teeth should be extracted.¹ Antibiotic coverage should be instituted prior to any contemplated surgery and continued through the primary healing phase (10-12 days).

The timing of radiation therapy following oral surgery is controversial. An interval of 10-14 days is usually adequate. The most important consideration is that the surface coverage of any exposed bone be complete before radiation starts.

Oral Care Following Radiation

Once the teeth have been exposed to radiation, all dental care thereafter should be conservative. Endodontics should be considered in lieu of extraction. Splinting may be useful in cases of mobility. If extraction is unavoidable, conservative surgical technique is mandatory and antibiotic coverage is indicated. Mandibular extraction sites are more vulnerable to postoperative complications.

Edentulous patients should not be considered for complete dentures for about one year following radiation therapy. Some patients may never wear a prosthesis. This is related to the severity

Fig. 2—An application of a 1% solution of sodium fluoride for five minutes is delivered by custom made mouth guards or individual plastic tooth covers. (A-top) Equipment for application of sodium fluoride; (B-middle) Tray ready to be seated; (C-bottom) Tray seated.

of radiation complication, jaw relationship, patient co-operation, etc. The alveolar ridges must be examined for smoothness and some return of salivary function should be present before a prosthesis is considered. The prosthesis itself should be constructed in such a way as to minimize ridge stresses. At the first sign of discomfort, the denture should be removed.

Complications and Their Treatment

Despite careful management, several complications can occur during and after the radiation period.

Caries

Caries is a definite postirradiation problem (Figure 3). Caries may be a direct effect of irradiation of the teeth,¹¹ or secondary to xerostomia.^{12,13} Frank related caries to the xerostomia and pointed out that patients did not have a massive destruction of tooth surfaces unless the salivary glands were included in the field.¹³ He also noted a reduction of pH of saliva when the glands were irradiated. The most important considerations in predicting caries activity in the patient receiving radiation to the oral cavity are: (1) original caries susceptibility, (2) gingival recession, (3) oral hygiene and, (4) dietary alterations during the irradiation period.

Fig. 3—Intra-oral photo demonstrating staining, plaque accumulation, and a definite post-irradiation problem.

Mucositis

Reddening of the oral mucosa or mucositis, and skin erythema are the first clinical signs following irradiation. Mucositis is a condition wherein the basal cell layer of the mucous membrane dies due to the radiation and produces a wide shallow ulceration.¹ It is not preventable and may be considered a necessary biological concomitant reac-

tion of radiation on a rapidly proliferating cell population. Mucositis is usually seen after a dose of about 2500 rads.⁹ The severity of the reaction is related to the total dose of radiation received, time period over which the radiation was given, volume and type of tissue irradiated, and modality used. Severe mucositis clinically has the appearance of white patches on an erythematous background¹ (Figure 4).

Fig. 4—Mucositis is seen clinically as white patches on an erythematous background.

Treatment of mucositis is symptomatic. Warm saline oral lavage will help keep the exposed sub-mucosa comfortable and clean. A soft diet, frequent fluid intake, and application of a topical anesthetic such as viscous xylocaine may be indicated.¹ A warm solution of one teaspoonful of Karo syrup and tap water is also soothing to the tissues, but has the disadvantage of the sugar contributing to caries.

Xerostomia

Xerostomia frequently develops during and after irradiation if the major salivary glands are included in the field. The role of the salivary glands in the production of this complication is not generally agreed upon. Initial changes in the parotid gland include destruction of the few mucous cells present followed by edema and parenchymatous degeneration of the serous acini.¹³ In the submandibular, lingual and minor salivary glands there is also a destruction of the mucinengorged cells with an immediate release of mucin. Continued irradiation brings about a complete or partial loss of mucin resulting in a scant, thin, and watery saliva. This absence of oral lubrication from mucin and a decrease in total saliva output are responsible for the xerostomia. Clinically, the intensity of the dryness increases with

tissue contact, spicy foods, fruits, alcohol, tobacco, carbonated beverages, and irritations.¹ A humidifier should be placed in the room and frequent intraoral fluids should be encouraged. Relief will also be obtained from substances which increase the lubrication of the oral tissues such as physiologic saline, mineral oil, or glycerine. Salivary flow may be stimulated by sugar free lemon drops. The duration of this condition is highly variable and is related to the dose and field of radiation.

Osteoradionecrosis

Osteoradionecrosis has been described as "a chronic unrelenting osteomyelitis of bone which has sustained radiation injury resulting in its inability to defend and repair itself."⁹ It was first reported in the United States in 1924 as associated with radium poisoning in watch dial painters.¹⁴

Bone damage following irradiation is the result of injury to the bone cells and vascular components. The exact pathologic process, however, is poorly understood.¹⁵ Generally, decreased osteoblastic and osteoclastic activities give rise to a diminished vitality in the affected areas. The bone forming and protective function of the periosteum is destroyed.¹⁶ Vascular damage may occur as a result of an obliterative endarteritis secondary to the radiation therapy.¹⁷

Anatomically, the blood supply to the mandible makes it more susceptible to osteoradionecrosis than the maxilla. Also the mandible has a larger percentage of compact bone and is more often in the line of radiation.

The incidence of osteoradionecrosis appears to have decreased since the introduction of super-voltage techniques. Watson and Scarborough reported in 1938 an incidence of 13% of 1,819 cases studied.¹⁸ Silverman in 1964, however, reported an incidence of only 3%.¹⁹ It is now believed that 2% or less of those patients receiving radiation where the mandible is in the field develop subsequent osteoradionecrosis.¹ The time of onset is highly variable. Cases have been reported as early as five months and as late as twelve years post-irradiation.^{11,18} The need for periodic recall of post-irradiation patients over an extended period of time is evident.

The early diagnosis of osteoradionecrosis is often difficult. The initial symptom is pain. Examination at this time may reveal an area of denuded, non-vital bone (Figure 5). Radio-

graphic diagnosis is unreliable. Stafne has stated that osteoradionecrosis cannot be differentiated from osteomyelitis of pyogenic origin.² The first radiographic evidence often occurs late in the disease process and may manifest as radiographic density is increased followed by evidence of osteolytic centers, pathologic fracture, and eventually sequestration² (Figure 6).

Fig. 5—Intra-oral photo of an area of denuded bone, a post-irradiation complication.

Fig. 6—Panoramic radiograph demonstrating the pathologic changes in osteoradionecrosis. On the left, osteolytic centers, pathologic fractures and sequestration of bone are evident.

Treatment of these lesions is also difficult. Small necrotic areas are best managed conservatively. Antibiotics may prevent an enlargement of the necrotic area and minimize secondary infection. Penicillin is probably the drug of choice. Since the healing of these lesions is very slow, antibiotic protection may be continued for weeks or months. Locally, peroxide glycerine preparations (Gly-Oxide) over the soft tissue ulceration will aid in keeping the area clean. This should be applied by the patient about four times daily. Curettage of small lesions is usually not indicated as the normal closure often breaks down and more radical procedures may then be necessary.

Infection

There is an increased incidence of oral infection related to those tissues receiving radiation. Some factors responsible for this increase include local erosion, necrosis associated with carcinoma or radiation, leukopenia associated with extensive radiation, poor diet and general debilitation.¹ Increased desquamation of the mucosa permits easy entry of oral bacteria.

Oral moniliasis is seen frequently. It is accompanied by symptoms of burning, tenderness, and dryness. Its appearance varies from that of a non-specific stomatitis to greyish-white necrotic patches. A culture is a helpful diagnostic aid. Treatment consists of mouth rinses after each meal and before retiring with mycostatin suspension or ointment (2 ml or 200,000 units).

Other local infection should be treated promptly. Any soft tissue ulceration over heavily irradiated bone can lead to osteoradionecrosis. Numerous topical anti-infectives are available including tetracycline, neomycin, polymyxin B, glyoxylate, and gentian violet. Any recurrent ulceration should

arouse suspicion and biopsy should be done to exclude recurrence of tumor, although biopsies of irradiated tissues may be unreliable.

General Care

The maintenance of the highest level of oral hygiene is essential. Adequate nutrition, often a major problem, must be maintained. Abstinence from tobacco and alcohol is important. However, compromises may sometimes be necessary.

Summary

Patients receiving radiation therapy involving the oral cavity and contiguous structures require specialized and individualized care under a team of experienced clinicians. The oral health problems of these patients are reviewed. The preparation of the oral cavity for radiation includes the removal of gross sepsis, extraction of questionable teeth, and patient education. During the radiation period the use of fluoride treatments, establishment of good oral health regimens including lavage and brushing, and maintenance of good nutrition are necessary.

"Independence Day"

The cover photograph of the night-time firework display at the Lafayette Club on Lake Minnetonka on the Fourth of July was taken by Dr. David J. Dunlap. He is an urologist, practicing in Minneapolis and on the medical staffs of North Memorial, St. Mary's and Unity Hospitals.

Every year at the Lafayette Club there is a fire display on the Fourth and people gather in their boats on the Lake in front of the Club observing the display. Dr. Dunlap told the editors he was at Bohn's Point directly across from the Club and used a time exposure to take the cover photo.

Acute Suppurative Thyroiditis

Report of Two Cases Including One Caused by *Mycobacterium Intracellulare* (Battey Bacillus)

RONALD OLIN, M.D.,* WAYNE E. LeBIEN, M.D.,* AND JOHN E. LEIGH, M.D.*

ACUTE SUPPURATIVE thyroiditis is a rare disease often difficult to diagnose in its early stages. It is much less common than subacute (DeQuervain's) and chronic (Hashimoto's and Riedel's) thyroiditis. Hamburger¹ in ten years of practice devoted to thyroid diseases, encountered only three patients with acute suppurative thyroiditis.

Suppurative thyroiditis was much more prevalent in the era before the liberal use of antibiotics. Boothby & Plummer² reported 24 cases occurring between 1910 and 1932. Young³ in 1940 found 26 cases of acute thyroiditis in 2900 thyroidectomies of which four were thyroid abscesses. In 1950, Altemeier⁴ reported ten cases of acute pyogenic thyroiditis. Hendrick⁵ in 1956 noted 28 cases of acute thyroiditis in 1309 thyroidectomies of which six were abscesses.

We have recently had the opportunity of seeing two patients with acute suppurative thyroiditis with abscess, including the case of a child from rural Minnesota in which *Mycobacterium intracellulare* was cultured. To our knowledge, this organism has not previously been reported to be associated with acute suppurative thyroiditis.

Case Reports

Case 1

A four-year old white girl who lived on a farm on the Minnesota side of the Minnesota-North Dakota border was seen in March, 1972, because of a painful, swollen thyroid gland which had come on suddenly one month previously. There was no history of a preceding upper respiratory infection. She had been afebrile from the onset and not ill otherwise. Tetracyclines, erythromycin, thyroid hormone and steroids had been given as one to two week trials of therapy but without benefit.

Physical examination revealed that the thyroid gland was diffusely replaced by a large, soft fluctuant mass larger on the left side. There was a firm, right supraclavicular node and shotty, bilateral, posterior triangular nodes.

Laboratory tests revealed the following: hemoglobin 12.6 gm.%; leukocyte count 9,800 per cmm. with a normal differential; sedimentation rate 47 mm. per hour (Westergren); normal or negative urinalysis, serum total thyroxine, T3 test and antithyroglobulin and antithyroid microsomal antibody titers. The I-131 uptake in 24 hours was 8% (normal 14 to 35%). Thyroid scan revealed "cold" areas. Chest Xray was negative; Xray of the cervical spine revealed soft tissue swelling in the anterior neck. A PPD intermediate skin test showed 1 x 1.2 cm. of erythema and 0.5 x 0.4 cm. of edema.

Three cc's of greenish, cloudy pus was aspirated from the left lobe area of the thyroid and sent for culture. The following day, under general anesthesia, the thyroid gland was entered through a transverse incision. There were three large abscess cavities all within the thyroid capsule. All cavities were widely opened and irrigated with peroxide and Betadine; two penrose drains were also inserted. The postoperative course was uneventful and she was dismissed without medication.

Cultures grew out *Mycobacterium intracellulare* (Battey bacillus) sensitive to INH, PAS and Streptomycin. It was then determined that the farm contained some poultry but no swine or cattle. None of the poultry had been ill. The child often helped pick eggs.

When seen for follow-up four months later she was feeling well. A small amount of pus was drained by unroofing a small ulcer in the incision and cauterizing it. The right supraclavicular node was smaller. Chest Xray remained negative; PPD intermediate skin test was still positive; the serum total thyroxine was again normal. INH was started.

Case 2

An 18-year old white man was hospitalized in April, 1969, because of pain, swelling, and tenderness of the left lobe of the thyroid gland of five days' duration. There was difficulty swallowing and he had been living on liquids for the previous two days. There was no preceding upper respiratory infection. Two years previously he had noted some swelling in the region of the left lobe of the thyroid gland which soon subsided without medical care.

Physical examination revealed a temperature of 102°F. The left lobe of the thyroid gland was enlarged three-fold, tender and fluctuant. The right lobe was normal size but tender. There was no cervical adenopathy.

Laboratory tests revealed the following: hemoglobin 15.1 gm.%; leukocyte count 8,600 per cmm. with 81% segs.; sedimentation rate 35 mm. per hour (Westergren);

*Departments of Internal Medicine, Pediatrics & Surgery, Fargo Clinic, Fargo, N.D.

See editorial, page 619.

normal urinalysis, serum PBI, total thyroxin and cholesterol. Chest Xray was negative. The I-131 uptake in 24 hours was 6% (normal 14 to 35%). Thyroid scan revealed a "cold" left lobe and irregular uptake on the right.

Five ml of purulent material was aspirated from the left lobe under local anesthesia. The patient then became afebrile and the thyroid gland returned to normal size. Cultures grew out *Staphylococcus epidermidis*, coagulase negative and *Streptococcus anhemolyticus*. Treatment consisted of Ampicillin 500 mg. orally every six hours for 10 days and desiccated thyroid hormone, two grains daily for two months.

Shortly after leaving the hospital, he saw his dentist who extracted one abscessed tooth, thus perhaps implicating the mouth in the pathogenesis of the thyroid abscess.

When seen for final follow-up six months later, he was feeling well and taking no medications. The thyroid gland was nontender and the outline of the left lobe was indistinct.

Discussion

Pathogenesis

Normally the thyroid gland has a remarkable degree of resistance to infection. It is completely encapsulated and thus not in direct communication with neighboring structures. It has an extensive lymphatic drainage and blood supply. The relatively high iodine concentration also provides an unfavorable environment for bacterial growth. Womack and Cole⁶ injected live staphylococcal and streptococcal organisms directly into the superior thyroidal artery of dogs and noted that even this rarely caused local suppuration.

Suppurative thyroiditis is invariably a secondary or metastatic phenomenon with the primary foci usually in the upper respiratory tract, face, mouth, and cervical nodes. The infection spreads to the thyroid via the lymphatics or blood stream. The fact that the arterioles of the thyroid are end arteries may favor implantation of septic emboli. Other methods of infection are by direct extension, sharp trauma to the anterior neck injuring the capsule, and rarely via a patent thyroglossal duct. Occasionally thyroid suppuration can occur in drug addicts who inject directly into the jugular vein.

The commonest organisms responsible for thyroid suppuration are the Gram positive cocci, namely, streptococci, staphylococci and pneumococci. *Mycobacterium tuberculosis*,⁷ *Treponema pallidum*,⁸ typhoid and paratyphoid bacilli,⁹ *Clostridial sp.*,¹⁰ *Actinomyces sp.*,¹¹ *Bacteroides*,¹² *E. coli* and Trypanosomes may cause suppuration in rare instances.

Suppurative thyroiditis may occur in a normal gland but is more common in a pre-existing goiter with one or more adenomas.

Clinical Manifestations

Women are more susceptible to thyroid suppuration than men in a ratio of 2:1. The most common age group is young adults, between 20 and 40 years of age. Patients present with the sudden onset of a painful, tender swelling in the anterior neck. Fever, chills, malaise, and dysphagia are common. The dysphagia is frequently referred to the ears, mandible, and occipital region. The patient may complain only of a sore throat and hoarseness. Physical examination reveals a localized or diffusely swollen and tender thyroid gland. The skin overlying the gland is often red and warm. The head is often held in the characteristic position described by Lahey in 1917 with the chin flexed to the involved side due to spasm of the neck muscles and in order to swallow. The swelling is at first firm, then fluctuant. Regional nodes may be involved. Occasionally, the neck is edematous so that the extent of the disease cannot be determined. The infection may subside spontaneously or proceed to abscess formation and spread in any direction. The danger is extension into the deep spaces of the neck with rupture into the mediastinum, trachea or esophagus. The prognosis is good as to life and adequacy of thyroid function.

Laboratory Tests

A polymorphonuclear leukocytosis and an elevated sedimentation rate are common. Patients are usually euthyroid in the acute phase. A thyroid scan can help in the differential diagnosis especially in separating suppurative adenitis; the area of thyroid suppuration is usually localized and functionless. The 24 hour I-131 uptake is commonly decreased. A discrepancy may exist between PBI and BEI values.¹⁴ With thyroidnecrosis, iodine-containing products spill into the blood and are measured in the PBI determination but not in the BEI.

Differential Diagnosis

Subacute thyroiditis is usually a milder disease and more often diffuse than localized. Serum thyroxine is likely to be elevated at the same time as the I-131 uptake is depressed. The differentiation from suppurative thyroiditis may be difficult in severe cases. Suppurative adenitis is also a less severe illness with the lesion more lateral and smaller. The thyroid scan is normal if the infection

has not reached the point of thyroid abscess formation. Hashimoto's thyroiditis has a gradual onset and the goiter is usually symmetrical and seldom large or very tender. Hemorrhage into a thyroid adenoma or cyst causes a painful, tender goiter but there is usually no fever or leukocytosis. Anaplastic carcinoma of the thyroid with tissue necrosis can be difficult to differentiate without histopathologic studies. If doubt exists about the diagnosis of acute suppurative thyroiditis, needle aspiration should be done.

Treatment

Treatment of suppurative thyroiditis consists of a combination of incision and drainage and appropriate antibiotics implemented early. The abscess is drained through a collar incision followed by a longitudinal incision through the prethyroidal muscles to the abscess cavity. Hendrick advised considerable care not to break down the walls of the abscess which could cause fatal mediastinitis. If multiple, loculated abscesses cannot be drained, partial or total thyroidectomy may be necessary.

Mycobacterium Intracellulare

Runyon Group III of atypical mycobacteria is made up of a heterogeneous variety of both pathogenic and nonpathogenic mycobacteria which do not develop pigment on exposure to light (non-photochromogens). Five subgroups are recognized of which *Mycobacterium intracellulare* is the best known. Synonyms are Battey-avian-swine complex, *M. avium* and Battey bacillus. This organism was first isolated at the Battey State Hospital, Georgia and is responsible for a pulmonary disease similar to that caused by *M. tuberculosis* and *M. Kansasii* although not occurring as frequently.¹⁶ Less commonly it can cause lymphadenitis, septic arthritis, tendinitis, skin lesions and fatal disseminated disease. Although infection with nonphotochromogens is said to occur most commonly in the southeastern part of the United States, some of the first reported cases involved patients who lived in Minnesota.¹⁷ Patients usually give a history of exposure to poultry, swine, or cattle. The best therapeutic results are obtained by surgical treatment. Chemotherapy seems to be of little avail.

Diagnostic Applications of Antinuclear Antibodies

Specifics and Non-Specifics

ABE L. FOX, JR., M.D.*

ANTINUCLEAR ANTIBODY detection has added both significant positive information and confusion to the differential diagnosis of clinical disease. There are several reasons for this.

1. Some antinuclear antibodies occur as a natural autoimmune phenomenon, unrelated to clinical disease. (Benign autoimmune phenomenon)
2. Some antinuclear antibodies are related directly to autoimmune diseases, and sometimes participate directly in the autoimmune disease process in the form of antigen-antibody complexes. (Disease-associative)
3. Other antinuclear antibodies occur incidental to autoimmune diseases. The antibodies have no direct or casual relationship to the disease process; their occurrence is incidental. (Incidental, non-associative)

These situations are partly separable by species identification of the antibody with specific nuclear proteins. Antibodies to the following nuclear antigens have been identified in association with clinical disease:

- "Native" DNA (double stranded)
- Denatured DNA (single stranded)
- DNA-histone (DNP)
- ENA (extractable nuclear antigen)
- Phosphate extractable antigens (Sm and others)
- Nucleolar

"Specific" Antinuclear Antibodies

Only *anti-"Native" DNA* has a high degree of specificity for the disease Systemic Lupus Erythematosus (S.L.E.). *Anti-"Native" DNA* antibodies are infrequent with other clinical diseases. Naturally occurring *anti-"Native" DNA* (benign autoimmune phenomenon) is apparently rare.^{4,6,9}

In contrast, *anti-Denatured DNA* antibodies are relatively common autoimmune phenomena and

occur frequently in association with drug induced Lupus syndromes, Chronic Active Aggressive Hepatitis, Rheumatoid Arthritis and less frequently with other collagen-vascular diseases. *Anti-Denatured DNA* antibodies are also common in S.L.E.⁴ Approximately 30% of patients with Systemic Lupus Erythematosus have antibodies to denatured DNA and no detectable *anti-"Native" DNA* antibodies.

"Speckled" fluorescent patterns of antinuclear antibody reaction and *anti-Nucleolar antibodies* are common in individuals with Progressive Systemic Sclerosis ("Scleroderma"). The former antibody is not *anti-Sm*.¹

ENA antibodies are prevalent in the "Mixed Connective Tissue Disease" syndrome and are also frequently found in S.L.E. The S.L.E. *anti-ENA* antibody-nucleoprotein reaction is RNA'se resistant; the Mixed Connective Tissue disease associated antibody reactions are RNA'se sensitive.⁷

L.E. Cell Preparation

The L.E. cell preparation is a complement dependent reaction detecting antibody to *DNA-histone (DNP)*. The L.E. cell prep is frequently positive in patients with S.L.E., drug induced Lupus syndromes, Rheumatoid Arthritis and other diseases. It is *not* specific for Systemic Lupus Erythematosus.⁵

Antinuclear Antibody Titers

The clinical significance of antinuclear antibodies is also closely correlated with the titer or concentration of the antibody in the serum. The absolute values of these "titers" varies considerably with the method employed to demonstrate the antibody (immunofluorescence microscopy, immunofluorescence macroscopic spot tests, precipitin tests, hemagglutination, radio-immunoassay), but it is valuable to consider "low" and "high" titers of antibody as they relate directly to the clinical

*Department of Pathology, Methodist Hospital, 6500 Excelsior Boulevard, St. Louis Park, Minnesota.
See editorial, page 622.

significance of the antibody and disease activity.

"High" titer antibodies are usually significant and indicate disease activity; "low" titers indicate decreased disease activity (e.g. treatment remission) or incidental phenomena.

Autoimmune Phenomena and Autoimmune Disease

"Naturally" occurring, disease associative, and incidental antibody phenomena are separable by combining clinical information, antibody species identification, antibody titer and other useful laboratory tests. A brief summary of these antinuclear antibody phenomena and disease follows. Included in Table 1 are serum complement, Rheumatoid Factor, and L.E. cell prep test results expected.

Antinuclear Antibodies Occurring as a Benign Autoimmune Phenomenon

Elderly Patient

Low serum concentrations of antinuclear antibodies are relatively common in elderly patients without disease. This phenomenon appears to be a result of aging only and is of no clinical significance.

Other

Younger individuals infrequently have "naturally" occurring antinuclear antibodies. The frequency of this serologic abnormality is difficult to determine statistically, or to interpret for the in-

dividual patient. Some of these patients may have latent or occult disease. Further laboratory and clinical evaluation is indicated.

Autoimmune Disease; Antinuclear Antibody Associative

Systemic Lupus Erythematosus

Antibodies to DNA are an integral part of Systemic Lupus Erythematosus. Immune complexes of anti-DNA and DNA are causally related to Lupus Nephritis.

Serum levels of anti-DNA vary with disease activity and treatment. Serum complement levels fall with the development of "soluble" (moderate DNA excess) immune complexes which bind complement. Hypocomplementemia is most common in patients with nephritis. Vasculitis with hypocomplementemia and no renal disease is less frequent. Specifically, anti-"Native" DNA antibodies are prevalent. Denatured DNA, DNA-histone, S_n and ENA antibodies are frequent but not specific.

Drug Induced Lupus Syndromes

Drug induced Lupus syndromes are associated with the development of antibodies to Denatured DNA.² While many of the clinical parameters typical of idiopathic Systemic Lupus Erythematosus are duplicated, nephritis is unreported and serum complement levels are uniformly normal. These findings imply that complement binding "soluble" DNA-anti-DNA complexes are not produced in significant quantities in drug induced

TABLE 1
Antinuclear Antibodies (A.N.A.)—Autoimmune Diseases

*Fluctuates with disease activity or treatment.

Lupus syndromes.

Anti-IGG antibodies (Rheumatoid factors) are also relatively frequent with drug induced Lupus syndromes. Both anti-DNA and anti-IGG antibodies disappear from the serum after the drug is stopped. Symptoms and antibodies may persist for variable periods of time but eventually dissipate.

Mixed Connective Tissue Disease Syndrome

This disease process is a complex of the clinical manifestations of S.L.E., Polymyositis and Progressive Systemic Sclerosis. The prevalent antibody identified is anti-ENA (RNA'se sensitive extractable nuclear antigen). Anti-DNA antibodies are also found. Nephritis and hypocomplementemia are unreported to date.⁷

Autoimmune Disease; Antinuclear Antibodies Incidental, Non-Associative

The extent to which "disease associative" antinuclear antibodies participate directly in S.L.E., drug induced Lupus syndrome, and the Mixed Connective Tissue Disease syndrome is not always measurable. However, it is clear that antinuclear antibodies in the following diseases occur as *incidental phenomena*. The diseases are not a result of antinuclear antibodies; the presence of antinuclear antibodies does not indicate some "variety" of Lupus. The antibodies produced are incidental, not associative.

Rheumatoid Arthritis

Anti-IGG antibodies (Rheumatoid Factors) are prevalent in Rheumatoid Arthritis but incidental antinuclear antibodies (anti-Denatured DNA) are also relatively common. In younger age groups (Juvenile Rheumatoid Arthritis) antinuclear antibodies are more common than Rheumatoid Factors. Serum complement levels are normal or increased in uncomplicated cases. L.E. cell preparations may be positive.

Chronic Active Aggressive Hepatitis

When chronic active aggressive hepatitis is accompanied by the serologic abnormality of antinuclear antibodies, it has been referred to as "Lupoid." The disease process is unrelated to Systemic Lupus Erythematosus and the term is unfortunate. Liver disease is unusual with S.L.E. and, when present, is rarely of the chronic active aggressive type.

The antinuclear antibodies produced are variable. Anti-Denatured DNA and DNA-histone antibodies (positive L.E. prep) are common. Serum complement is normal or high. Clinical

evidence of joint or renal disease is negligible. *Progressive Systemic Sclerosis (P.S.S.)*

Antinuclear antibodies with "speckled" nuclear patterns of reaction (not Sm) are common in patients with P.S.S. ("Scleroderma"). Nucleolar antibodies are less frequent, but are more specific. Anti-DNA and/or anti-DNP antibodies are relatively uncommon. The malignant hypertension renal lesion of P.S.S. is not associated with hypocomplementemia. The significance of antinuclear antibodies in this disease is unclear.

Polyarteritis, Dermatomyositis, Polymyositis, Autoimmune Thyroiditis.

Antinuclear antibodies may have some importance in the evolution of these diseases but the incidence of measurable antinuclear antibodies is low and probably insignificant.

Differential Anti-DNA Testing

The value of differential testing for anti-"Native" and anti-Denatured DNA antibodies is apparent. Detection of anti-"Native" DNA antibodies is positive presumptive evidence for Systemic Lupus Erythematosus. Anti-Denatured DNA antibodies occur in many disease processes, including S.L.E. Identification of Anti-Denatured DNA antinuclear antibody in a patient's serum should increase clinical suspicion of S.L.E., but is not specific.

We have recently devised a modification of the Friou immunofluorescent spot test³ for differentiating antibodies to "Native" and Denatured DNA. Serial dilutions of the patient's serum are incubated with equal aliquots of "Native" and heat denatured calf thymus DNA (Worthington Biochem).

The antibody species and clinical diagnosis of M.H. inpatients tested March 1-November 1, 1972 are paired in the tables. Of 310 in patients screened, 65 patients had antibodies to DNA; eight of these 65 had anti-"Native" DNA antibodies; 57 had anti-Denatured DNA antibodies. Fifty-five of the 65 patients were females (see Table 2).

TABLE 2
Methodist Hospital Antinuclear Antibody Screens
March 1-Nov. 1, 1972

Total Inpatients Tested	310
Anti-"Native" DNA	8 (8F.)
Anti-Denatured DNA	57 (47F.)

Seven of eight patients with anti-"Native" DNA antibodies were diagnosed clinically as Systemic Lupus Erythematosus. Only four of 57 patients with anti-denatured DNA antibodies had clinical manifestations of S.L.E. (see Table 3).

TABLE 3
Methodist Hospital Patients—Anti-DNA Antibodies
March 1-Nov. 1, 1972

Anti-"Native" DNA	8

"Other"	1
Anti-Denatured DNA	57
Clinical DX SLE	4
"Other"	54

Nineteen patients were 60 or over. Two of the 19 had high titer antibodies to denatured DNA. Of the two "elderly" patients with high titer anti-Denatured DNA antibodies, one had Systemic Lupus Erythematosus, the other Rheumatoid Arthritis. Seventeen of the 19 elderly patients had no clinical evidence of autoimmune disease (see Table 4).

TABLE 4
Methodist Hospital Patients—Anti-Denatured DNA
March 1-Nov. 1, 1972

Clinical Diagnosis		(High titer)
SLE	4	(2)
Rheumatoid Arthritis	8	(3)
P.S.S.	1	
Drug Induced Lupus Syndrome	2	(1)
Auto Immune Hepatitis	1	
Lung Disease	4	
Other (includes sarcoidosis, malignancies, infection, FUO, misc.)	20	(None)
Elderly patients (60+)	19	(1-S.L.E.; 1-R.A.)

The most common clinical disease of patients with anti-Denatured DNA antibodies was Rheumatoid Arthritis (8/57). Systemic Lupus Erythematosus, drug induced Lupus syndrome, autoimmune liver disease and other diseases were present in this group.

Though the number of patients is relatively small, the selective specificity of identifying anti-"Native" DNA antibodies is evident. Of the eight patients with anti-"Native" DNA, only one was not clinically diagnosed as S.L.E. In retrospect, this patient has many of the clinical features of S.L.E. and may manifest this disease, or some other, more clearly in the future.

Less than 10% of the patients with anti-Denatured DNA antibodies had Systemic Lupus Erythematosus (4/57). The vast majority of these patients had other autoimmune processes or "benign" phenomenon, not S.L.E.

Friou reviewed several authors' anti-"Native" DNA antibody test results and found 28 of 4,859 patients with non Lupus autoimmune disease were reported to have low titer anti-"Native" DNA antibodies, an incidence of less than 1%. Thirteen of

these patients had Rheumatoid Arthritis and several had Sjogrens syndrome. Single cases of Polyarteritis Nodosa, chronic active hepatitis, multiple myeloma and "chronic glomerulonephritis" were also reported.⁶

Summary

1. Low titer antinuclear antibodies occurring in elderly patients are usually insignificant. In the absence of clinical disease, low titer antinuclear antibodies should be interpreted as a naturally occurring "benign" autoimmune phenomenon in this population.
2. Low and high titer antinuclear antibodies in other than elderly patients are usually *not* naturally occurring immune phenomena. These patients should be evaluated carefully for possible autoimmune disease or drug history.
3. Anti-"Native" DNA antibodies are most common in patients with Systemic Lupus Erythematosus. However, some patients with S.L.E. have antibodies to denatured DNA only.
4. Anti-Denatured DNA antibodies are frequent in autoimmune diseases other than S.L.E.:
 - a. In some instances the association with the disease process is relatively constant and probably directly related. (Drug induced Lupus syndrome)
 - b. In some instances the anti-nuclear antibodies appear to occur as an incidental phenomenon, without constant or direct association with the disease process. (Chronic Active Aggressive Hepatitis. Rheumatoid Arthritis etc.)
5. Antinuclear antibody *titers* generally correlate with disease activity. High titer anti-nuclear antibodies do not indicate Systemic Lupus Erythematosus unless the antibody specificity is anti-"Native" DNA. Low titer anti-nuclear antibodies may reflect disease remission (e.g. treatment) or incidental phenomena.
6. Results of a differential anti-"Native" and anti-Denatured antibody test are reported. A high degree of correlation between anti-"Native" DNA antibody and the clinical diagnosis of S.L.E. was found. Less than 10% of patients with anti-Denatured DNA antibodies had S.L.E.

Treatment of Testicular Tumors

ELWIN E. FRALEY, M.D., COLIN MARKLAND, M.D. AND KAILASH KEDIA, M.D.

NEOPLASMS OF THE testicle are classified according to their probable cell of origin; that is, germinal and non-germinal cell tumors. Germinal tumors are the most common testicular tumors in adults. The four main histologic types of germinal neoplasms are seminoma, teratocarcinoma, embryonal carcinoma, and choriocarcinoma.

Even though germinal tumors may have a common origin, they are usually subdivided clinically on the basis of their malignant potential and their response to treatment. For example, seminomas are extremely radio-sensitive and, therefore, treatment is orchidectomy and radiation, even with metastatic disease. The cure rate of these tumors approaches 90 percent in most series. The non-seminomatous germinal cell tumors are more ethal, and therapy requires a multidisciplinary approach, using surgery, radiotherapy, and chemotherapy.

This paper presents our recent experience with non-seminomatous germinal cell neoplasms of the testis, with special emphasis on surgical treatment.

Patient Material

From 1964 through 1971, 35 patients with malignant non-seminomatous testicular tumors have been treated. The patients ranged in age from two to 60 years, and none have been lost to followup.

Presenting Symptoms

It has been written and taught that most testicular tumors are painless. However, 24 (69 percent) of these patients had pain and swelling in the testis as the earliest signs of their disease. Furthermore, five (14 percent) had pain only. The remaining six (17 percent) became alarmed by a painless enlargement of the testis and this finding

alone prompted them to see their doctor.

In almost one-half of these patients, the nature of the disease was not immediately recognized by the patient's physician. In extreme cases, diagnosis was delayed three to six months.

Pathology

The histologic findings in these cases are summarized in Table 1.

TABLE 1

Tumor Type	Total No.	Pathology		Mortality
		With Pos. Nodes	With Neg. Nodes	
Embryonal	11	5	6	1
Terato Ca	6	4	2	1
Mixed	17	9	8	2
Teratoma	1	—	1	—
Total	35	18	17	4

Treatment

The treatment of these tumors is surgical, often augmented with radiotherapy and chemotherapy.

Surgical treatment of these neoplasms begins with the approach to the primary lesion. If a testicular tumor is suspected, the patient should be explored through a groin incision so that the cord can be cross-clamped at the internal ring before the testicle is mobilized. Next, the testicle and all of its connective tissue coverings are delivered into the wound. At this point the testicle is further isolated by covering the wound with towels. Every precaution must be taken to prevent these highly malignant tissues from 'seeding' the wound. In most cases, the neoplastic nature of the lesion is evident but, if a confirmatory biopsy is indicated, it is done by placing the distal cord and testicle in a pan and the biopsy is carried out as a "dirty" procedure. If the testicle is malignant, nothing that touches the tumor is used again. In fact, it is important to change gloves and gowns after the biopsy before completing the orchidectomy. The cord is divided as proximal as possible using electrocautery and the cut ends are fulgurated also to

This paper was presented before the Spring meeting of the Twin Cities Urological Association, April 29, 1972.

See editorial, page 621.

avoid the slightest chance of contamination. The proximal end of the cord is suture ligated and the sutures are left long so they can be identified at the subsequent radical retroperitoneal node dissection.

A suspected testicular tumor should never be biopsied using a transscrotal incision. The lymphatic drainage of the scrotum is to the superficial and deep inguinal nodes and to the lymphatics of the anterior abdominal wall. Thus, if a testicular tumor is inadvertently biopsied through the scrotum, the tumor can gain access to lymphatic drainage fields different from those of the testis and definitive therapy becomes more difficult. When a testis tumor has been biopsied or when a tumor has been removed using a scrotal incision, we refer to the wound as 'contaminated'.

One unusual aspect of our series is that 14 of our cases had 'contaminated' orchiectomies. As recently described by Markland,¹ this problem must be dealt with by a hemiscrotectomy, a wide excision of the inguinal area and a radical inguinal lymph node dissection. If the spermatic cord has not been excised completely, it should be removed. This operation is carried out before the retroperitoneal node dissection is done.

The retroperitoneal nodes can be approached either through the abdomen or transthoracically. The transthoracic technique was used throughout this series for several reasons. First, the transthoracic approach provides the best exposure to the lymphatics along the great vessels above the ipsilateral renal pedicle. Since the primary lymphatic drainage of the testicle is to the ipsilateral renal pedicle, the dissection must begin well above the renal hilum. Second, by reflecting the intact peritoneum medially, the entire procedure can be done so that there is no possibility of contaminating the abdominal cavity with tumor cells. Third, even though this approach involves opening the thoracic cavity, there is little morbidity.

The initial incision is made through the bed of the eighth or ninth rib, and carried medially across the ipsilateral rectus muscle, dividing the muscle and rectus sheath. Another gently curved incision is then made lateral to the rectus connecting with the upper incision and extending into the lower quadrant (Figure 1). After the peritoneum is retracted medially, complete exposure of the retroperitoneum allows an 'en bloc' retroperitoneal dissection, which encompasses the adrenal gland and

Fig. 1—This is a postoperative photograph of a patient who presented with a 'contaminated orchiectomy'. The incision of the hemiscrotectomy, inguinal orchiectomy and superficial groin dissection are shown. The upper incisions are those described in the text which are used for the retroperitoneal node dissection.

is fascial coverings, the connective tissue envelope of the kidney, the tissues in the ipsilateral renal hilum and the paravertebral lymphatics and lymph nodes (Figure 2). All patients in this series had radical, transthoracic lymphadenectomy. There were no operative deaths.

If the retroperitoneal nodes are tumor-free, usually no additional therapy is given. If lymphatic metastases are present, the patient receives radiation or chemotherapy or, on occasion, both. The mode of supplementary therapy is determined by the histology of a primary tumor as well as the histology of the metastases. For example, if the primary tumor and the metastases are pure embryonal carcinoma, the patient is treated postoperatively only with Mithramycin.* But, if the primary tumor is a teratocarcinoma or a mixed tumor and if the metastases have a similar histology, usually the patient is given radiation to the retroperitoneum mediastinum, and the left supraclavicular region. An alternative to radiation therapy in this latter situation is triple drug chemotherapy as recently reported.² All cases are reviewed carefully by a team representing the disciplines of pathology, radiotherapy, medical oncology and urology.

Table 2 summarizes the various therapies given to patients in this series.

Results

Of the 35 patients treated since 1964, six were followed for more than six months and 24 were followed for more than one year. The remaining five patients were followed less than six months, but they are all free of disease. Thus far, four patients have died of their cancer and 31 are alive and free of tumor. This is an overall survival rate of 87.1 percent. The results obtained in this series and in similar groups of patients from other institutions are summarized in Table 3.

All 17 patients with negative nodes are alive and well. Fourteen of eighteen patients with positive nodes are alive and well. Thus, approximately 78 percent of patients with positive nodes are

Discussion

Until recently a diagnosis of non-seminomatous testicular cancer caused terror in the patient and his doctor. However, as reported herein and by others,³⁻¹⁰ multimodal therapy permits a new outlook for this disease. Whereas, in the past, treatment by radical orchiectomy and radiation alone produced an overall cure rate in non-seminomatous tumors of approximately 30 to 40 percent,⁵ now combined treatment with radical surgery, radiation, and appropriate chemotherapy has more than doubled the patient's chance for survival. Possibly even these figures can be improved as discussed herein.

A general principle in cancer is that early diagnosis gives the best chance for cure. When diagnosis in testicular cancer is delayed it is usually either because the patient pays little attention to

minimal early symptoms or because a physician fails to recognize the significance of a solid testicular mass. Although testicular cancer may be mistaken for a variety of abnormalities, it is more frequently misjudged as epididymitis, hydrocele, or hernia. In general, if there is any question as to the diagnosis of any scrotal mass, especially in young men, testicular cancer always should be excluded.

Of course, another possible consequence of incorrect diagnosis is that the testis may be explored and biopsied through a transscrotal incision. This report previously emphasized the seriousness of this error, pointing out that the skin of the scrotum and its lymphatics may be contaminated with tumor. Because the lymphatic drainage of the scrotum is different from that of the testis,

scrotal contamination of longstanding is almost impossible to treat by radical surgery alone. Fortunately, most of these patients are seen early and the ultraradical technique of hemiscrotoectomy and inguinal node dissection offers a chance to prevent the potential complication of local tumor recurrence.

An additional important aspect of this disease that must be recognized if results are to be improved, is that these patients require a therapeutic 'team' consisting of surgeons, radiation therapists and medical oncologists. The advantage of the 'team' approach is clear from the improved survival figures not only in our patients but in other series as well. Because this is an uncommon tumor there is a need to accumulate and treat these patients under uniform conditions so that further refinements in treatment can be developed.

Steroid-Induced Mediastinal Lipomatosis

GUAN C. CHONG, B.Sc., M.B.B.S., TALBERT COOPER, M.D., AND
W. SPENCER PAYNE, M.D.

WIDENING OF THE mediastinum due to deposition of benign fat is rare. That the fat deposition could be induced by prolonged treatment with high doses of corticosteroids has only recently been recognized;¹ however, 17 such cases have been reported in the past five years.¹⁻⁶ The true incidence of steroid-induced mediastinal lipomatosis is not established. Its apparent rarity may be related both to a lack of physician awareness and to the subtlety of clinical presentation. The present case report illustrates the clinical vagaries of the condition.

Report of Case

In December 1968, a 61-year-old Caucasian man was found to have positive results to Coombs' test and a diagnosis was made elsewhere of chronic hemolytic anemia. The genesis of this problem was indeterminate and empiric therapy with prednisone (40 mg daily) continued for the ensuing 17 months. The hemoglobin level ranged from eight to 12 gm/100 ml of blood during this period. The addition of azathioprine (Imuran) therapy for approximately one month was of no measurable benefit. In April 1970, when the patient was first examined in the Mayo Clinic, changes denoting Cushing's syndrome were apparent. No significant enlargement of superficial lymph nodes, liver, or spleen was detected.

Hematologic studies including positive Coombs' test affirmed the earlier diagnosis of hemolytic anemia. Roentgenograms of the chest showed no evidence of abnormality (Figure 1). Left supraclavicular nodes were removed and tissue sections showed nothing more than nonspecific inflammatory changes. Twenty milligrams of nitrogen mustard were administered intravenously and prednisone in a dosage of 20 to 40 mg daily was continued.

When the patient returned for reexamination in February 1971, the changes of Cushing's syndrome were increased. Roentgenograms of the chest showed widening of the superior mediastinum (Figure 2), and the possibility of lymphoproliferative disease was again considered. Lymphangiography, however, disclosed no abnormalities, but minor nonspecific filling defects were present in several femoral and iliac lymph nodes. Radioisotopic scans of liver and spleen appeared normal.

Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

Fig. 1—Standard roentgenogram of chest in April 1970 after patient had been treated with steroids for 18 months; physical examination showed a moderate cushingoid appearance.

Fig. 2—Standard roentgenogram of chest made in March 1971 demonstrated widening of the superior mediastinum at mediastinoscopy.

Mediastinoscopy performed with the patient under general anesthesia, disclosed no significant lymphadenopathy but the superior mediastinum appeared to be infiltrated with fatty tissue. The nature of the tissue was confirmed on microscopic examination. Immediately thereafter exploratory laparotomy revealed no gross abnormalities but splenectomy was performed as a possible palliative measure for the idiopathic hemolytic process. Except for moderate hemosiderosis, sections of the spleen were free of abnormalities.

The dosage of corticosteroid was gradually reduced and finally discontinued in July 1971. Three months later a roentgenogram of the chest showed significant regression of the superior mediastinal widening (Figure 3). The patient then was symptomatically improved and the hemoglobin level was 15 gm/100 ml of blood.

During February 1972, his physical features appeared normal. Mediastinal widening was further reduced and laboratory studies provided evidence of a well-compensated hemolytic process.

Comment

Steroid-induced mediastinal lipomatosis was first documented by Koerner and Sun in 1966.¹ The condition is benign and apparently represents another facet of the centripetal deposition of fat seen in Cushing's syndrome. The clinical entity has been reported both in patients taking high doses of steroids^{1,3,6} and in Cushing's syndrome due to adrenal tumors.^{4,5} Usually the mediastinal widening is an incidental finding and causes no symptoms. All the patients with this condition showed development of moderate to severe, steroid induced features. Recognition of the condition is possible from serial roentgenograms of the chest, showing a gradual progressive development of a smooth and symmetric widening of the anterior superior mediastinum over months or years. Other

radiologic features include enlarged pericardial fat pads and the lack of extrinsic pressure effect on the airways. Confirmation of the diagnosis has rested on open thoracotomy,^{1,2} autopsy,² regression of mediastinal widening with withdrawal of steroids^{4,5} and, in the case presented here, mediastinoscopy and biopsy. *Since this is a benign condition, the suggested approach is confirmation of the diagnosis by mediastinoscopy.* Subsequent regression on follow-up roentgenograms of the chest made after corticosteroid medication had been discontinued for at least three months provided further confirmation in this case. Mediastinal widening, however, erroneously suggested the possibility of lymphoproliferative disease.

Fig. 3—Roentgenogram of chest made in November 1971 nine months after discontinuing steroid therapy. Mediastinal widening had regressed.

Mesodermal Mixed Tumor of the Corpus Uteri*

JOHN A. REICHERT, M.D.†

IN THE SHORT PERIOD from July 1, 1971 to December 1, 1971 three cases of mixed mesodermal tumor of the uterus were encountered at Hennepin County General Hospital. Although Piquand,¹ in 1905, stated that the ratio of this rare tumor to all malignancies of the uterine corpus was 1:7,500, more recent reports have indicated that this tumor is more common. In our hospital the ratio of mesodermal mixed tumors to all corporeal malignancies from 1940-1971 was 1:58.

Case Reports

Case 1

A 65-year-old, para 7-0-3-7 and 12 years postmenopausal was admitted with vaginal bleeding of two months' duration and increased bleeding and passage of tissue on the day of admission. Pelvic examination found the cervix 4 cm. dilated and containing a friable mass. The mass was biopsied and a D&C done. Both the biopsy tissue and the endometrial curettings were interpreted histologically as mixed mesodermal tumor. An abdominal hysterectomy and bilateral salpingo-oophorectomy were performed. The uterus measured 13 x 8 x 6 cm. and contained a polypoid tumor mass 3 x 4 x 2 cm. arising from the posterior wall of the corpus (Figure 1). Histologic sections showed involvement of myometrium but the tumor did not extend to the serosa.

The postoperative course was unremarkable and 17 months later there were no signs of recurrence.

Case 2

A 76-year-old, para 1-1-1-1 and 30 years postmenopausal, was admitted to the hospital with a brown vaginal discharge of five weeks' duration. Examination found the uterus irregular and about 16 weeks' gestational size.

A D&C produced only necrotic tissue. An abdominal hysterectomy and bilateral salpingo-oophorectomy were done. The uterus measured 14 x 6 x 9 cm. and one cut section showed light tan tissue infiltrating the myometrium (Figure 2). Histologic sections identified this as a mixed mesodermal tumor.

Twelve months after surgery the patient was asymptomatic with no evidence of recurrence.

Fig. 2—Tumor shown infiltrating the myometrium.

Fig. 3—Autopsy specimen with uterus opened, pointer on cervix.

Fig. 4—Typical cross striations of rhabdomyocyte.

Case 3

A 57-year-old, para 3-0-1-3 and 18 years postmenopausal, was admitted to the hospital with nausea, emesis and weight loss for six weeks. Pelvic examination found an atrophic closed cervix. There was no bleeding from the os. Bimanual examination found a cystic mass arising from the pelvis and extending to the umbilicus. Following stabilization, a D&C was performed and the mass identified as the uterus. Forty cc. of tissue and 200 cc. of blood and purulent material were removed from the uterine cavity. At exploratory laparotomy extensive adhesions and local extension of the tumor made resection impossible. The patient expired on the second postoperative day following a massive pulmonary embolus.

At autopsy the uterus measured 24 x 20 x 18 cm. and weighed 3,700 grams. The tumor appeared to arise just above the cervix and histologically was a mixed mesodermal tumor (Figures 3 and 4). There was infiltration of neoplastic cells into the serosa of both the large and small bowel and encircling the right ureter.

Classification

The diagnosis and management of mixed mesodermal tumors have represented an enigma to the gynecologist. That they are relatively rare but highly malignant has been well established, but the assignment of over 100 different names to these tumors partially reflects the confused appreciation of their true nature.² Essentially, a mixed mesodermal tumor is composed of specialized mesodermal tissue. In the past, this designation has been applied to a variety of uterine neoplasms including sarcoma botryoides, carcinosarcoma, endometrial stromal sarcoma, and only rarely to a specific neoplasm characterized by the presence of heterologous mesenchymal elements.^{3,4,5,6} Heterologous in this instance refers to a tumor composed of elements which have no benign counterpart in the uterus (i.e., elements, such as fat, striated muscle, bone, cartilage, etc.)

Incidence

The rarity of this tumor can be appreciated by the recognition that sarcomas make up about one percent of all uterine cancers, and mixed mesodermal tumors represent about 15-20 percent of uterine sarcomas.^{3,7} The greater diagnostic success in recent years is undoubtedly due to an increased awareness of the lesion and a high index of suspicion.

The literature indicates that patients represent all races and have a wide range of parity from nulligravid to grandmultiparity.⁸ The mean age

s about 60 with the vast majority postmenopausal.⁹

In most series, between 10-25 percent of patients have had a previous history of irradiation—usually for benign uterine bleeding^{6,8} or carcinoma of the cervix with a usual lag period of 5-20 years.¹⁰

Gross

The tumor generally arises from the endometrium of the posterior wall with rapid growth projecting into the cavity as a solitary or multiple growth and often resembling a benign polyp as represented clinically by the first case.¹¹ When more advanced, as demonstrated by the second and third cases, areas of necrosis and hemorrhage may be found with infiltration of tumor into the myometrium and beyond to the serosa.⁴

Histology

Microscopically, these tumors show considerable variations in structure and in different parts of the same tumor. Usually the sarcomatous part of the mixed tumor predominates, although areas containing epithelium, benign or malignant, are not uncommon.^{11,12} The sarcomatous features include: (a) Rhabdomyosarcoma, (b) Osteogenic sarcoma, (c) Chondrosarcoma, (d) Liposarcoma and (e) Embryonal sarcoma.

Metastases

Generally, the tumor is confined to the uterus when first diagnosed, but extension through the myometrium and serosa with involvement of contiguous structures in the pelvis and abdomen is not uncommon.^{11,12}

This spread indicates a predilection for local extension of the tumor, but lymphatic and hematogenous metastases are not rare.^{9,13} Generally, distant metastases are to the lungs and liver of either sarcomatous or carcinomatous elements—occasionally of both.^{3,11}

Histogenesis

Histogenetically, the mixed mesodermal tumors are thought to arise from multi-potential cells within the stroma that have the capacity to differentiate into both epithelium and stroma. The stromal cells, by virtue of this inherent metastatic potential, can undergo transformation to

other types of mesenchymal cells, such as cartilage, striated muscle or osteoblasts, thus forming the heterologous elements so prominently displayed in mixed mesodermal tumors.^{3,6,14}

Symptoms and Signs

Bleeding and discharge are the most common symptoms for which these postmenopausal patients seek medical help. The median duration of these symptoms is two months. Abdominal or pelvic pain may be present, and when the tumor is advanced, intestinal symptoms and weight loss may be observed. About 75 percent of patients have enlargement of the uterus when first seen. In about 25 percent of the cases, viable tumor may be seen within the cervical canal or protruding from the external cervical os.^{4,8,11}

Diagnosis

A punch biopsy of the mass presenting in the cervix or a D&C establishes the diagnosis in approximately 50 percent of cases in which it is done. In the remainder the large amount of necrotic tissue may prevent diagnosis. Sarcoma or adenocarcinoma is often the initial diagnosis on curettage specimen.⁸

Prognosis

The majority of these tumors recur within a year, although occasionally the first recurrence is three to five years after treatment. The overall five-year survival varies from report to report but usually is 15-20 percent.^{8,9}

Treatment

Many different types of treatment have been employed for mixed mesodermal tumor. Most oncologists believe that radiotherapy offers very little if any control of this neoplasm. Adequate and prompt operation is the treatment of choice and should consist of a total abdominal hysterectomy and a bilateral salpingo-oophorectomy. To the present time, chemotherapy has been of little value, although palliative results in sporadic cases have been reported using cyclophosphamide.⁹

Conclusions

The highly malignant nature of this tumor has been well established. Unfortunately, the symptoms appear when the tumor is already in an advanced biologic stage.

The duration of symptoms, the histologic grade, and the anatomic extent of the tumor have all been used as prognostic indices. The findings of extension beyond the uterus at laparotomy makes the outlook for survival almost hopeless. There are instances, however, in which lesions have extended beyond the uterus yet have survived over five years.

Whether or not radiation therapy may be etiologic in the development of this malignancy is

speculative. Irradiation therapy for dysfunctional bleeding is seldom used today, but irradiation therapy is the preferred mode of therapy in many clinics for carcinoma of the cervix. It will be interesting to see whether there is a decreased incidence of these tumors in the years to come.

The hopes for increased cure rates would seem to rest not only in earlier diagnosis but also in newer therapeutic approaches.
